

This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world's books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that's often difficult to discover.

Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book's long journey from the publisher to a library and finally to you.

Usage guidelines

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

We also ask that you:

+ *Make non-commercial use of the files* We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.

+ *Refrain from automated querying* Do not send automated queries of any sort to Google's system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.

+ *Maintain attribution* The Google "watermark" you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.

+ *Keep it legal* Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can't offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book's appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

About Google Book Search

Google's mission is to organize the world's information and to make it universally accessible and useful. Google Book Search helps readers discover the world's books while helping authors and publishers reach new audiences. You can search through the full text of this book on the web at `http://books.google.com/`

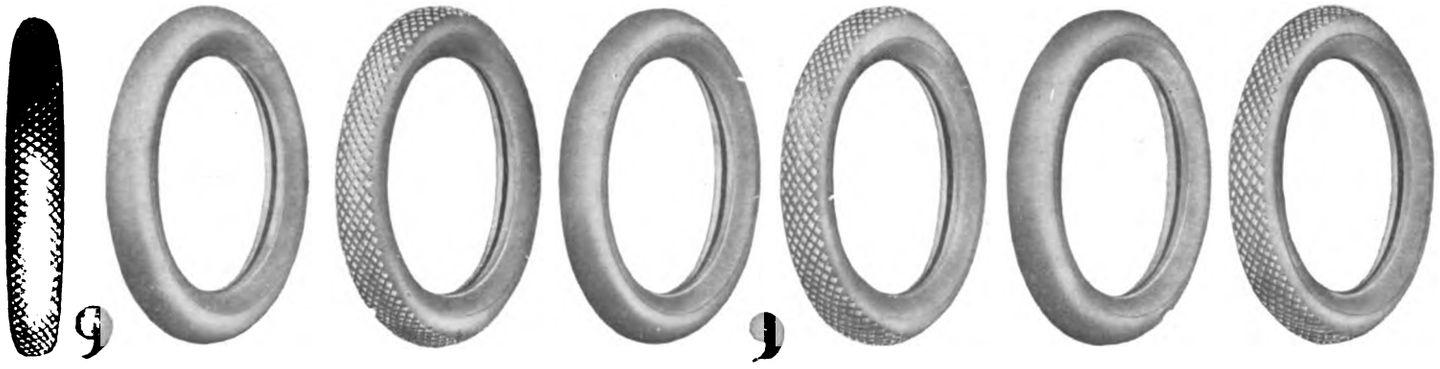
THE 1912



Pierce-Arrow

TOURING CAR

is a delight to the eye in body designing. The last link that connected the automobile body with coach building has been severed, and the PIERCE-ARROW *has a body growing out of its natural needs as an automobile.*

The Pierce-Arrow Motor Car Co., Buffalo

Published Weekly by The Motor World Publishing Company, 1600 Broadway, New York

No-Rim-Cut Tires—10% Oversize Touch the Million Mark

This month we celebrate. A million Goodyear Auto Tires have now gone into use.

Over half that million have been sold within the past 12 months. Yet this is our 13th year.

Think what that means. More sold in this last year alone than in 12 years put together.

Just because No-Rim-Cut Tires—our patented type—suddenly became the sensation.

A few men proved them out. Then thousands proved them—then tens of thousands more.

Now a million tires. Now a trebled demand over last year. Now a larger sale than any other tire commands.

All this occurs after these tires have been tested on some 200,000 cars.

The Reign of the New Type Tire

Now comes the reign of a new-type tire—a tire that cuts tire bills in two.

A tire that can't rim-cut—an oversize tire, to save the blowouts due to overloading.

A hookless tire—one that needs no tire bolts, nor hooking to the rim.

And a tire which embodies the final results of our 13 years spent in perfecting tires.

All these features combined in a tire which costs no more than other standard tires.

That will explain this overwhelming demand for Goodyear No-Rim-Cut tires.

Old-Type Tires Must Go

Old-type tires—clincher tires—rim-cut when partly deflated. When they run flat, because of a puncture, a minute's time may wreck them.

Statistics show that 23% of all ruined clincher tires have been rim-cut.

Now comes a type which makes rim-cutting impossible. And all of you motorists are sometime bound to adopt them.

These same tires—No-Rim-Cut tires—are made 10% oversize. The hookless base permits that.

That means 10% more air—10% greater carrying capacity—without any extra cost.

It means support for your extras, and for passengers who overweigh. It reduces the danger of blowouts.

That 10% oversize, under average conditions, adds 25% to the tire mileage.

All those advantages at the price of tires which lack them. How long will any man cling, in your estimation, to old-type, skimpy tires?

The Secret

The secret of this new-type tire lies in three flat bands of 126 braided wires.

These braided wires are vulcanized into the tire base. Thus the tire base is made unstretchable.

This tire needs no beads to hook into the rim flange, because nothing can force the tire over the flange.

But, unlock the flange and the tire slips off like any quick-detachable tire. It slips off much easier, because no beads can get "frozen" into the rim flange.

With this hookless tire, your removable rim flanges are slipped to the opposite sides. Then they curve outward instead of inward.

Instead of a curved flange digging into the tire there is a rounded edge on which the tire rests if deflated.

There is no changing of rims if your rims are standard. Nearly all rims are now made to fit these tires.

We Control It

This braided wire feature forms the only way to make a practical tire of this type. The reasons are explained in our Tire Book.

Competition, of course, has forced other makers to attempt this hookless tire. But the essential feature is controlled by our patents. And substitute features have proved unsatisfactory. Many have been abandoned.

This new-type tire, if you want it right, means the Goodyear No-Rim-Cut tire. That is why the demand, in a flood-like way, has centered on this tire.

Get the proved-out tire when you get this type. Get the tire which outsells all the rest after a million have gone into use.

Our 1912 Tire Book—based on 13 years spent in tire-making—is filled with facts you should know. Ask us to mail it to you.

Letter No. 8

Manufacturers and Dealers Motor Fire Insurance Company
(TO BE INC.)

Manufacturers and Dealers Motor Casualty Company
(TO BE INC.)

1402 North American Building
Philadelphia

March 28th, 1912.

Messrs. MANUFACTURER, DEALER and COMPANY,
Every City, Everywhere.

Gentlemen--

QUALITY SERVICE--WHAT DOES IT MEAN TO YOU IN YOUR BUSINESS?

IT MEANS something more than delivering to your customer a satisfactory car.

IT MEANS that you are at all times prepared to render your customer such service as will eliminate all possible annoyance which he might experience through the ownership of this car.

IT MEANS that you must be able to advise him about any accessories which he may want--furnish them if he so desires; in fact, be his advisor in all things pertaining to his car and GIVE HIM SUCH ADVICE AS TO INSPIRE HIS CONFIDENCE IN YOU, and thereby HOLD HIM AS A CUSTOMER for all time.

ARE YOU EQUIPPED to advise your customer, authoritively, with reference to some form of insurance and feel assured that your advice will not return to plague you?

ARE YOU EQUIPPED to arrange for this insurance should your customer request you to attend to it for him?

WRITE US.

Yours very truly,

ORGANIZATION COMMITTEE,
By Ernest H. Greenwood, Secretary.

P. S. Look for letter number 4 on this page next week.

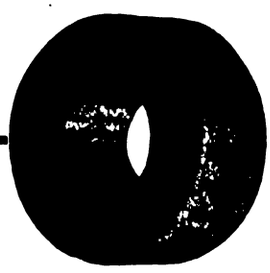
MAY WE HAVE YOUR LAYOUT

Of Bearing Installation?

¶ We can save you money, time and trouble—in other words, show you a short cut to satisfactory bearing installation.



¶ The successful use of New Departures in 60% of the motor cars manufactured in this country proves that the quality of this American made bearing has been well established.

¶ This fact also constitutes a good reason why you should send us your layout and give our engineering and sales departments an opportunity to place our proposition squarely before you.

¶ Our engineering department is highly specialized, not only for the production of superior ball bearings, but for giving to the trade expert co-operative service.

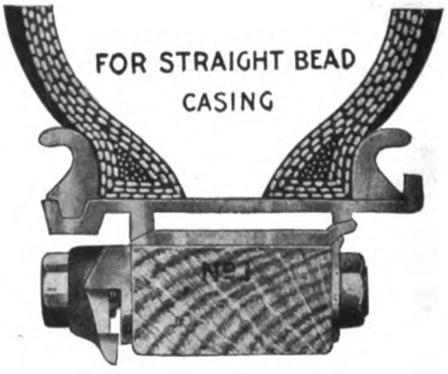
THE MOST DIRECT WAY

TO REDUCE YOUR TIRE TROUBLE IS TO USE

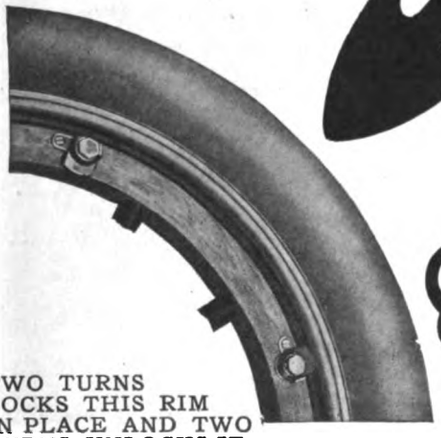
Absolutely Universal

THE FEATURE that makes this rim universal is the fact that the side rings are reversible so as to accommodate either straight side or clincher tires.

The rim is demountable. Two turns of a nut locks or unlocks it. It is quick detachable, aside from its demountable feature.



The Car Manufacturer is not limited in the sale of his car on account of types of tires when using STANDARD UNIVERSAL RIMS—all tires fit these rims.



The Car Owner has an unlimited market from which to select his tires.

The Tire Maker is not handicapped in his sales—all tires fit STANDARD UNIVERSAL RIMS.

Send for our catalogue No. 607 explaining quick detachable and demountable rims.

TWO TURNS LOCKS THIS RIM IN PLACE AND TWO TURNS UNLOCKS IT FOR DEMOUNTING

"The Horn that's Made for the Discriminating"

TUTO HORN

THE TWO TONE HORN

Economical in Current Consumption

THE TUTO Horn with its patented "two-tone" feature and one-button control is acknowledged the most adequate signal for the modern motor car.

¶ The completeness and neatness of the TUTO Horn mounting equipment has stamped this device as superior to all other warning signals, in its adaptability to all makes of cars.

¶ The protection of the wiring and the locking of the operating parts from working loose make the TUTO Horn positive in operation and entirely dependable.

¶ The electrical energy required for operating the TUTO Horn is so small as to be practically negligible—less than one ampere on the low note and below two amperes on the high note. Under average conditions, the low note is used 90 per cent of the time, so that the TUTO Horn is without question, the most economical electrical warning device marketed.

¶ Low current consumption is absolutely essential for any warning signal which is used for standard equipment in the place of the bulb horn. The TUTO displaces both the bulb and the single-tone-loud electric horns, thus it is used constantly where all other types of electrical warning signals are used only occasionally as a supplement to the bulb horn.

¶ Yet with this constant use, the TUTO Horn will operate from four months to a full season on one set of five standard No. 6 dry cells, or from one to two months on one charge of a small ignition storage battery.

¶ The TUTO Horn, furthermore, can be operated from any six volt lighting or starting battery with equal economy.

¶ In comparison with other electrical warning signals, the one-loud-note-type, the TUTO requires from 1-2 to 1-12 as much energy for its operation. In other words, the battery will last from two to twelve times as long.

¶ This low current consumption is another vital reason for the adoption of the TUTO Horn as standard equipment on all motor cars.

GOING SOME

A nigger met a ghost on the road and it chased him. The darkey ran till he was out of breath and then flopped down to rest. "We were sure going some," said the ghost. "Hungh — dat ain't nothin' side o' what we're goin' to go when ah gets mah breff," replied the terrified darkey.

The *Stewart Speedometer* has been "*going some.*" Its only *real* competitor has been its own shadow. We have given the world the *best* speedometer that could be made and sold it for the price of the *least;* but the past performances of the *Stewart Speedometer* won't have a "*ghost*" of a show with its *future.*

Money can't *make* the Stewart better; and money can't *buy* the Stewart's *better.* The price is *little* because the output's *big.*

Built the *strongest* — lasts the *longest.*

On *four* cars out of five, and—"*We're about to go sum mo'.*"

Speedometers, $15 to $30
Clock Combinations, $45 to $70

Magnetic principle—jewel bearings—wearing parts hardened and polished; open dial—large figures, easily read—absolutely accurate; 100,000-mile season odometer, 100-mile trip register, can be reset to any tenth of a mile. Guaranteed for five years. Strongest flexible shaft—drop forged swivel joint—noiseless gears.

"ALWAYS ON THE JOB."

"When I Bought My Car"

"One of the first mechanical details I looked into was the bearings," an owner was heard to remark recently to a friend who was in the market.

"The car I owned had Hyatt Roller Bearings in the rear axle where the hardest strains and jolts are received. I drove that car over one hundred thousand miles in three years and never even saw the bearings."

"Screw down the grease cups once in a while, so that there is ample lubrication, and your car will run on Hyatt's for years."

Hyatt Roller Bearings afford a line contact and because of their flexible principle, give a perfect bearing surface. Specifications show Hyatt's in 91 out of 100 cars built in America this year.

Unquestionably there is a big advantage in a dealer being able to say to his customers—

I am going to sell, this year, tires made as no other tires in the world are made and they will cost you no more than you are asked to pay for other kinds.

I have arranged with four of the world's leading tire factories to build me a tire for your use that actually combines every element of strength and every secret of manufacture known to the four factories.

In these four immense, completely equipped plants there are at work for me today four corps of tire specialists each of which formerly made a brand of tires which ranked among the world's best tires—Continental, G & J, Hartford and Morgan & Wright.

These experts have combined all their skill, all their knowledge, all their tire building experience to produce one uniformly superior brand of tires—UNITED STATES TIRES, in every one of which there is the Strength of Four.

The United States Tire line is a big one. It includes the three most popular and reliable styles of fastening—Quick Detachable, Dunlop (straight side) and Clincher—and six styles of tread.

These are the tires I am handling this season. Why not try them?

Tire-by Satisfied thank you

The Atwater Kent Ignition System

YOU might be excused for wasting batteries and littering up your car with fussy ignition equipment, if to do so contributed to the better running of your car or to your comfort and peace of mind.

Kick Switch Coil

But when you accept a vibrator coil and timer outfit or a cheap magneto on your new car instead of an Atwater Kent System, you are doing more than running up a bill for battery renewal and charging. You are saddling yourself with a train of small worries and uncertainties, delays for tinkering and necessity for renewals, all of which *were* a part of the game a few years ago, but which are unnecessary now.

The automobile of the future will have an ignition system as reliable as any other part of the car. Most of them will use the Atwater Kent System.

Perhaps an Atwater Kent outfit is all that is needed to make that old car run better than new.

Write today for booklet "D"

Dealers—Here is the 100% Efficient Self-Starter You Can Install on Every Car in Your Territory—READ THE REASONS

Retail Price $20. Your Profit Most Liberal

PRACTICALLY every car owner in your territory wants a self starter, but heretofore prices have been too high, installation too difficult and unreliability most pronounced. Here are reasons why you can change this condition into one approximating cold cash for you.

FIRST REASON—The Crankless Self Starter equals the best high-priced device—is more efficient than the ordinary contrivance and starts the engine 100 times out of a hundred by simple foot pressure.

SECOND REASON—**There isn't a car owner, cranking by hand, who will not welcome your suggestion to equip his car with the simplest self starter on the market at a price he can afford to pay—that price is $20.00.**

THIRD REASON—You, Mr. Dealer, or even your customer, can attach the Crankless Self Starter—easily—quickly.

FOURTH REASON—Every Crankless Self Starter you install will be a traveling advertisement for you—it will sell others—we guarantee this.

FIFTH REASON—We have a proposition that is good enough to make you want to join us in the work of putting the best and most dependable starter on several hundred thousand cars that ought to have them.

Fill out the corner coupon and we will return you a money-making proposition—one you can turn into quick, profitable action.

The Car the Public Wants

Versus

The Difficult Car to Sell

Model "N"

The Regal "25" Underslung Roadster $900

THERE ARE A LARGE NUMBER OF DEALERS—dealers whose selling abilities are unquestioned, who are not doing the maximum amount of business they are capable of doing, for one very important reason—they waste their energies upon difficult cars to sell. By that, we mean, they represent cars that have not enough distinction in quality, price or design to easily beat competition.

THE PUBLIC is very critical. People are educated in motor car values. They have fancies and we might say, educated prejudices. It is absolutely certain, any car today that wins public confidence, so that it outsells all others in its particular field, must have a certain distinct quality, superiority, call it what you will, as a reason for its pre-eminence.

THE REGAL "25" UNDERSLUNG ROADSTER is one of the select number of cars the public wants. Thousands have been sold because this car **has** that distinctive quality, that superiority which results from advanced engineering construction. This car has, in fact, **outsold** all other Roadsters because of these inbuilt values and because it is marketed at a moderate price.

SUPPOSE A DEALER HAS TEN PROSPECTIVE BUYERS, to whom he thinks he could sell Roadsters. But, suppose the manufacturer of the particular car he represents does not specialize (very few do) but builds Roadster bodies upon Touring Car chasses, is it not a difficult matter to convince each and every one of those ten possible purchasers that this makeshift Model is the car he wants? Seven out of those ten purchasers will know that the ideal Roadster must be designed and built a Roadster from the ground up.

THE EASY CAR TO SELL is the car that most closely approaches perfection. We affirm this Regal "Underslung" Roadster to be not only as near perfect a Roadster as is possible to build, but, owing to its "Underslung" construction to be superior in design to any Roadster built the ordinary way. "Underslung" construction gives it that distinctive beautiful appearance, that comfortable look, despite the raciness and suggestive power in its lines, making this car the biggest seller of its class in the country.

THE COMPREHENSIVE REGAL LINE is an answerable business argument to any dealer who is abreast of the times—who studies public preference—who does not waste the powers of his organization selling cars that are difficult to sell. There is a Regal Model to suit every taste, to meet every demand for moderate priced cars. What is more to the point, they are **"Underslungs"** with all the advantages of "Safety," "Economy," and "Comfort," this advanced construction implies. Our enormous and growing business proves they are easy to sell, because they are the cars the public wants.

SOME "UNDERSLUNG" ROADSTER SPECIFICATIONS—Motor 25-H. P.; 3¾ x 4½; Wheel Base 100 inches; Magneto and Batteries (dual ignition); Transmission (Selective) Hyatt Roller Bearings throughout Transmission and Axle; Three speeds forward, one reverse; Morgan & Wright Tires, 32 x 3½; Standard Equipment; five lamps; Generator; Horn; Complete Tool Equipment; (Folding Glass Windshield and Mohair Top and Top Boot $50 extra.)

OTHER REGAL "UNDERSLUNGS"—Regal "25" Underslung Touring Car $950. (The talk of the New York and Chicago Shows.) The Famous Regal "25" Underslung Colonial Coupe $1250. The Regal "35" "Underslung" Touring Car $1400.

Do You Know What the Hayes Service Will Do For You?

We are the largest sheet metal users in the world. Our factories, making all-metal automobile bodies, wood-metal bodies, fenders, aprons, dashes, shrouds, running boards, hoods, gasoline tanks, battery boxes, tool boxes, etc., are equipped to extend the most valuable service that the automobile maker can enlist.

Hayes Fender of Latest Design

Our engineers are ready at all times to give you valuable advice on bodies or fenders. They will go over your blueprints with you, suggest and advise and in every way help your designers to a better solution of some of your producing problems. Our new equipment, which is only just completed, enables us to do more toward putting cars through an automobile factory in quick time than any service we know of. We are prepared to take the entire sheet metal proposition off the makers' hands at a saving of money, and better still, to the prevention of the wrath of automobile dealers who during the rush season are demanding delivery of cars. We fit fenders, aprons, dashes, shrouds, running boards, right to your chassis, so when you receive them in your factory there is no time whatever lost in assembling these parts.

To the fenders we fit fender irons, which minimize vibration and rattle.

We guarantee every department of the Hayes service, the same as we guarantee Hayes materials. The Hayes standard is inflexible. The Hayes service is complete. Help your factory production by taking advantage of our new and wonderful facilities. Let us make you a sample set of parts for your car from your blueprints.

Let us prove to you what the Hayes service will do for your business.

The Human Equation In Good Axle Building

It takes 3633 separate operations to make a Timken-Detroit Rear Axle for pleasure cars—588 operations to make a front axle for pleasure cars.

A majority of these operations require accuracy within half a thousandth part of an inch.

The great Timken-Detroit plant is equipped with the latest automatic machinery and the most accurate jigs, tools, gauges and measuring instruments. As far as can be done the possibility of human error is eliminated in the making of the parts. That is Timken policy.

But it never will be possible to entirely, or even really very largely, eliminate the human equation from the manufacture of a complex article such as the rear axle of an automobile. The wonderfully exact machines must be set *by men*. The parts must be inspected after each operation, *by men*. The completely assembled axle must be tested *by men*.

It all comes right down to the man-stuff of the organization.

It is demonstrated fact, not mere theory, that there is a limit to the number of new men who can be "absorbed" into the Timken-Detroit Organization. Men who can get the Timken Spirit.

And it is demonstrated fact that the Spirit is even more necessary to the production of Quality than are machinery, tools, material and capital.

The Timken-Detroit Axle Company

Detroit, Michigan, U. S. A.

The only axle manufacturer licensed to make axles equipped with the famous Timken Roller Bearings

COLBYS GET BACK THEIR COMPANY

Deal With Ten-Million-Dollar Implement Company is Unexpectedly Dissolved—W. M. Colby Resumes Presidency.

Despite the official announcement made in December last that interests identified with the Western Implement & Motor Co., of Davenport, Ia., had acquired the controlling interest in the Colby Motor Co., of Mason City, Ia., it transpires that the transaction was not so closely knit as to prevent its easy dissolution, and hitches or friction which developed have served to bring about such a state of affairs. By mutual consent the deal has been declared off and the new officers who were elected in December have retired and the Colby interests returned to full control of the company bearing their name. Following this action, William M. Colby was elected president; James A. Colby, vice-president, and H. S. Murphy, secretary-treasurer and general manager.

William M. Colby was the original head of the company, but in December last he retired in favor of J. E. Burmeister, who is treasurer of the Western Implement & Motor Co. At the same time, W. N. Smith and H. S. Murphy, sales managers for the Implement company were made secretary and treasurer, respectively, of the Colby organization. With the abandonment of the transaction of December first, Smith, like Burmeister, has retired from the Colby company, but Murphy remains and with enlarged power.

The Western Implement & Motor Co. is the possessor of a Delaware charter and has an authorized capital of $10,000,000, equally divided into common and preferred. Within the last three months it has been offering for sale $1,000,000 of its preferred shares, and giving as a bonus a half share of common with each preferred share.

The company has outlined for itself some ambitious and far-reaching plans, which included even the establishment of a model manufacturing village, which was to be named Appleby, after one of its promoters.

Ohio Cars to Be Built in Canada.

Negotiations which have been progress for some time with the Board of Trade of Colborne, Ont., looking to the establishment by the Ohio Motor Car Co., of Cincinnati, of a Canadian plant, finally have been consummated and the Canadian company is in process of organization. It will be incorporated with $400,000 capital, of which $250,000 will be common stock and $150,000 preferred. The factory, of course, will be located in Colborne, which is situated on Lake Ontario, 84 miles east of Toronto. Charles F. Pratt, president and general manager of the parent company, will have an active part in the management of the Canadian project. Plans for its factory building already have been completed and work, it is stated, will be started immediately.

Palmer Joins the Chevrolet Company.

R. A. Palmer, who resigned the general management of the Cartercar Co. some months ago, ostensibly to become associated with the Savings and Loan Association, of Detroit, of which he is an officer, has become identified with the Chevrolet Motor Car Co., which is one of W. C. Durant's projects. For the present, Palmer will not state what position he will hold or what are his intentions or the intentions of the company. "Just say that I have joined the Chevrolet company," is the substance of his response to all inquiries.

Elmendorf Heads New Michigan Company.

The Manistee Auto Co. has been organized in the Michigan city of that name to manufacture a low-priced runabout and a light delivery wagon. Charles Elmendorf is president and general manager of the enterprise, which is capitalized at $51,000, and George N. Burr, is secretary-treasurer. The company has acquired a disused factory building at River and Fifth streets, in Manistee, and is making ready to install the necessary machinery, which already has been purchased.

PARTING OF COLE AND HENDERSON

Correlated Manufacturing and Sales Companies to Go Separate Ways—One Henderson Will Build Cars.

On July 1, according to good authority, the intimate relations which exist between the Cole Motor Car Co. and the Henderson Motor Sales Co., of Indianapolis, whereby the latter markets the entire output of Cole cars, will be terminated.

At the same time, according to the same authority, the Henderson brothers, Chas. P. and R. P., president and vice-president, respectively, of the Henderson company, will go separate ways, which, however, will not bring them into serious conflict. Chas. P. Henderson will become general sales manager for the Cole Motor Car Co., while R. P. Henderson will head a new organization, which probably willl be styled the Henderson Motor Car Co., and which will produce a car of its own, entitled the Henderson. There will be no Cole money whatever in the new Henderson company, nor will Charles P. Henderson have any interest whatsoever in it.

When R. P. Henderson was asked by a Motor World man whether this information was correct, he said that at this time he cared to say nothing whatsoever concerning the matter. He refused either to deny or confirm the reports.

"On Friday of this week," he added, "an official statement will be issued which will fully explain matters; until that time I must be excused from saying anything."

The new Henderson car will not be a direct competitor of the Cole; nor will it be ready for the market until very late in the season. Probably it will not make its official debut until shortly before the New York show in January. That it will sell for a lower price than the Cole is certain, however. In fact, the desire for a lower priced model and one which will net the R. P. Henderson interests, at least, a better profit than it has obtained under the pres-

Digitized by Google

ent arrangement, appears to have been one of the causes, if not the chief cause, leading up to the present state of affairs.

Just where the new Henderson company will locate is not certain, but there is every likelihood that it will find a home in Indianapolis. It will sell its product direct through its own staff and not through the Cole agents. Chester S. Ricker probably will be chief of the engineering department.

Already there has been a slight shake-up in the staff of the Henderson Motor Sales Co., whereby Homer McKee will, on April 1st, become advertising manager, while H. C. Bradfield will continue in charge of the publicity bureau.

Electrics Merged But Details Lacking.

Concurrent with the filing of papers certifying to the dissolution of the Buffalo Electric Carriage Co., of Buffalo, N. Y., late last week there was incorporated, under the laws of New York, the Buffalo Electric Vehicle Co capitalized at $1,000,000, the dissolution and the incorporation having a direct bearing on each other. It is stated that the new million dollar corporation represents a merger of five Buffalo concerns which will engage in the manufacture of electric vehicles of all types, but all efforts to discover the identity of the five concerns were discouraged and brought no result. According to the papers filed, the directors are W. P. Seipp, W. C. Feuchter, Thomas Wheeler, Frank E. Lane and Marcus Alexander, all of Buffalo, but several of them who were approached by a Motor world man declined to give any information, referring the inquirer to the company's attorney, who also refused information. He stated that it would be at least ten days before the company would be able to give the names of the five companies which are concerned in the merger. Of the capital stock of the new company, $700,000 is common and $300,000 preferred.

Toole Strikes at Gearless Steering.

Alleging that he had been deceived, and that the article which it proposed to manufacture is worthless, Samuel Toole has applied to the Superior Court in Indianapolis for a receiver for the Gearless Steering Device Co., of that city. He also asks for a judgment of $15,000 against W. E. Kurtz, J. A. Kurtz and H. H. Fulton, the directors and sponsors of the company, which sought to make a so-called gearless steering apparatus for motor cars. In his complaint, Toole states that he became interested in the company through a newspaper advertisement, and that on investigation was told that $14,171 had been expended on the plant and that it had a working capital of $12,500. On the strength of this and other representations he was induced to invest $11,000 in the company which he now denounces. He alleges that it has considerable machinery and other property in storage, and asks that a receiver be appointed to take charge of its assets and to render an accounting.

DID DYER "HOLD OUT" ON A. L. A. M.?

Likely That Such a Charge Will Mark Litigation Over His Patents—Most Vital Patents Were Pending.

Although the litigation instituted by the Enterprize Automobile Co., of New York, which practically is another name for Leonard H. Dyer, and which involves the Dyer direct drive and sliding gear patents, Nos. 885,986 and 921,863, has not even reached the stage of taking testimony, those who desire to make mountains out of molehills are finding it a fertile field for their purpose.

The patents are far reaching in their scope, but the situation has not changed since the Motor World, in December last, published the first news regarding them.

The main suits, as was then stated, are directed against the Locomobile Co. of America, Winton Motor Carriage Co. and Maxwell-Briscoe, Inc., but as the Dyer interests have served summonses also on about 400 individual owners, wherever desire exists to inflate and exaggerate, the returns from these comparatively petty proceedings render it possible to give to them an importance they really do not possess.

As the three defendant manufacturers are members of the Automobile Board of Trade, which fell heir to A. L. A. M. affairs, the suits are being defended by that organization, and although the complaints were instituted about a year ago the answers have not yet been filed. There are indications, however, that when they are filed, apart from other defenses which may be set up, the Dyer interests will be accused of having committed what practically amounts to sharp practice in their negotiations with the Association of Licensed Automobile Manufacturers.

As the Motor World stated in its story of December last, the A. L. A. M. had acquired from Dyer a license to convey to such of its members as desired it the right to operate under five Dyer patents, all of them having to with change speed levers and certain forms of gearing. The two patents which the Dyer interests have brought to bear against the Locomobile and Winton companies and Maxwell-Briscoe were not included in the contract. As a matter of fact, they were then pending in the Patent Office and there are those who allege that the A. L. A. M., when it executed its contract, had no knowledge of their existence and entered into the agreement with Dyer believing that the five patents included in the agreement covered the entire range of the Dyer inventions. The awakening of the A. L. A. M., it is stated, did not occur until the present litigation first was threatened.

Regardless of other defenses which may be interposed, it is fairly certain that this phase of the matter holds possibilities for criminations and recriminations, and that the testimony is likely to be possessed of sharp edges. Meanwhile, the litigation remains in status quo and the "invitations" which are being extended by the Dyer interests to individual owners to step up and settle at $25 per "settlement" have little, if any, bearing on the merits of the case, and serve chiefly to provide pegs on which to hang exaggerated publicity.

In addition to the suits pending against the Locomobile and Winton companies and Maxwell-Briscoe, there also is pending an action, instituted by Dyer, against the Palmer & Singer Mfg. Co., involving his patent, No. 657,650, covering a guide plate for change speed levers, which patent is one of the five included in the A. L. A. M. contract. Although members of the A. L. A. M., Palmer & Singer did not acquire the shop rights which were open to them and this suit is, of course, separate and apart from those involving patents Nos. 885,986 and 921,863.

Date Set for Sale of Jonz Plant.

Unless a satisfactory proposal is received meanwhile, the plant of the American Automobile Co., in New Albany, Ind., will be disposed of at public sale on April 14, the receiver having been authorized by the courts to take such action. Creditors and stockholders who have claims against the company have been given until May 14th to file their claims. The American Automobile Corporation, which is being formed by men identified with the old company, probably will bid in the plant, which, during its brief career, turned out more "clink of gold" certificates than Jonz motor cars, which it expected to produce.

Elmore Men to Make Krebs Trucks.

The Krebs Commercial Car Co., of Clyde, Ohio, which recently was organized by men previously associated with the Elmore company, of that city, has completed its organization by electing the following officers: B. A. Becker, president; George Slessman, vice-president; Homer Metzger, secretary; Robert B. Jones, treasurer; J. I. C. Krebs, general manager. The company will produce a truck of 1,500 pounds capacity, which will employ a two-cylinder, two-cycle block motor, the dimensions of which are 4½x5 inches.

Morgan & Wright Buy More Property.

The old factory of the Olds Motor Works, in Detroit, which until recently was used by the Welch Motor Car Co., which also is a General Motors possession, has been sold to Morgan & Wright for a consideration of approximately $100,000. The property, which directly adjoins the Morgan & Wright plant, is 200x1,100 feet, and its acquisition is accepted as presaging an enlargement of the Morgan & Wright factory.

AMPLEX SECURES RIGHT TO AXLE

After Long Fight With Packard, Court Sustains Its Contentions—The Type of Construction at Stake.

After a protracted struggle over patent No. 904,744, which was carried through the various ramifications of the patent office until it reached the Court of Appeals of the District of Columbia, the Simplex Motor Car Co., of Mishawaka, Ind., manufacturer of the Amplex car, has been judicially confirmed in its right to the exclusive use of the rear axle casing construction covered by the patent, which has been employed both by the Simplex company and the Packard Motor Car Co., of Detroit, for several years. The Simplex interests won every stage of the interference proceedings, but the Packard people refused to surrender and carried the case higher each time.

The sectional construction of the built-up rear axle casing was the issue at stake. The axle is made up of four sections, two of which are joined to form the central housing enclosing the bevel driving gears and the differential, the other two being the end sections, upon the outer extremities of which the bearings for the wheels are carried. The inner ends of the outer sections are made with tubular sleeves which telescope into corresponding receptacles in the central housing, the telescoping parts serving not only to join the various sections together, but also to provide supports for the bearings on which the inner ends of the driving shafts are carried and to prevent the egress of the oil which otherwise could work along the hollow arms and find its way out through the wheel bearings. The patent in question was granted November 24, 1908, and is owned by the Simplex company.

Briscoe Denies the Thomas Rumor.

Because the same financial interests which took over the old E. R. Thomas Motor Co., of Buffalo, about a year ago, are also heavily interested in the United States Motor Co., the report was spread broadcast this week that the latter had formally embraced the Buffalo company and would make Thomas cars the leader of the United States line. President Briscoe, of the United States Motor Co., however, declares that the rumor is unfounded. He states that the Thomas company is no closer to the United States company than it was a year ago.

Pittsburgh Capital Invested in Engines.

Pittsburgh capital having been interested in the Model Gas Engine Works, of Peru, Ind., a branch factory is to be established in the Pennsylvania city, negotiations to that end already having been completed. F. F. Nicola, W. C. Coffin, J. T. Keenan, J. G. Vilsack and O. J. Vilsack are the Pittsburghers concerned in the project, two of them at least being men of considerable wealth. They are said to have invested $300,000 in the Model company, which hereafter will build only the higher grade of engines. It is stated that among other large contracts recently secured is one from the Baldwin Locomotive Works, which will employ Model engines on all of its gasolene propelled railway apparatus. E. A. Myers, general manager of the Model Gas Engine Works, is at present in Pittsburgh selecting a site for a factory in that city and completing other necessary arrangements. He will be in full charge of both plants.

Carhartt Sued on Contract for Motors.

Suit for $20,000 was instituted on Saturday last in the Circuit Court of Wayne County, in Detroit, by the Continental Motor Mfg. Co., of Muskegon, Mich., against the Carhartt Automobile Corporation, of Detroit. The complaint alleges damages for breach of contract, and grows out of a contract made March 15, 1910, for 200 motors at $244.50 each. Of this number but 42 were accepted by the Carhartt corporation, which, according to the complaint, requested the Continental company to delay the manufacture and delivery of the others, and March 17th last year, canceled the contract. The Continental Motor Mfg. Co. agreed to the cancelation, provided the defendant company would pay for the cost of material and labor which had been expended on its accounts. As, despite repeated requests, this has not been done, the Continental company has been forced to go to law to recoup itself.

Willys Buys Control of Gramm Trucks.

For some time it has been known that John N. Willys, president and owner of the Willys-Overland Co., of Toledo, was contemplating the development of a truck of his own and the establishment of a truck factory, but finally he has decided to do neither. Instead, he has purchased a controlling interest in the Gramm Motor Truck Co., of Lima, Ohio, which is not merely a growing concern, with a complete line of commercial vehicles, but which has been established for many years and already has acquired a reputation. The Gramm plant comprises 6¼ acres under roof and employs 1,200 men. The consideration involved has not been made public. Although Willys has acquired control, B. A. Gramm, president of the Gramm company, will remain in direct charge of the Lima plant.

Again Enlarging Timken-Detroit Plant.

The Timken-Detroit Axle Co. has broken ground for a four-story addition to its plant on Clarke avenue, Detroit, which, when completed, will increase the factory capacity 25 per cent. The new structure will be of brick and steel, 65x150 feet, and will be ready for occupancy June 1st.

KRUPP MOTORS WORKED IN SECRET

But German Steel Company Draws Them Into Limelight—Infringement Suit Brings Disclosures.

Light soon may be shed upon the assets, activities and intentions of the Krupp Motors Co., of Pittsburgh, Pa., as the result of a suit for infringement of the "Krupp" trademark, which was filed against it last week in the United States District Court at Wilmington, Del., by Thomas Prosser, 15 Gold street, New York City, the accredited Krupp agent for the United States. For some time past the Krupp Motors Co. has been one of the mysteries of the trade. All that was known of it was the report that it was looking for a factory site, and that it claimed to have purchased ten acres at Beaver Falls, Pa. It had offices in the Jenkins Arcade building in the "Smoky City," but no intimation was vouchsafed to inquirers as to when or where its "Krupp" automobiles, "Krupp" cars and "Krupp" steel cars were to be manufactured.

Despite this slight drawback the company, according to the statement attributed to its president, boasted of a wonderful business. All the $250,000 stock issued is said to have been sold, and one of the large Chicago banking houses is alleged to have offered to take over an entire bond issue of $5,000,000, if the company would create one. The Krupp Motors Co., however, spur-r-ned the offer; it would create no bonded indebtedness; it had bought 10 acres of land for a factory site and would pay $40,000 for it, when "the title was passed." A plant to cost $600,000 would be erected on the site, President Morgan declared, but how the $250,000 stock issue was to pay for the $600,000 plant and the necessary manufacturing operations he failed to explain, unless the explanation lies in the assertion that the company, while endeavoring to hide its light under a bushel, contracted for 250 cars to be shipped to Australia, 350 to Chicago and 450 to parties in Pittsburgh. The company is stated to have had considerable trouble in keeping its projects and plans from the papers, and that it was far from looking for advertising, etc. All of which information, and a good deal more, is contained in an affidavit filed in connection with the suit, which is made out by David L. Raine, of New York City, who, on March 2, interviewed D. Morgan in his office in the Jenkins Arcade building.

During the course of the interview the caller was informed, he claims, that the name "Krupp" was utilized for the reason that the officers of the Pittsburgh concern knew what Krupp steel was and what it stood for. The name, accordingly, was of value. Raine further declares that a large lithograph of the Krupp works in Essen,

Digitized by Google

Germany, was hanging on the wall in Morgan's office when he called.

It is set forth in the bill that the defendant, "with intent to deceive and mislead the public and purchasers, and cause them to believe" that the Krupps of Germany made its products, has advertised "The Krupp Automobile, "The Krupp Car" and "Krupp Steel Car." It is alleged that this is in violation of the complainant's exclusive right to the word "Krupp" as its trademark.

Besides Morgan, the only names mentioned in connection with the company are G. H. Anderson and James McMorran, stockholders.

Elmer and Lohr Move "Six" to Cleveland.

H. H. Elmer, one time general manager of the Haynes Automobile Co., of Kokomo, Ind., who, with several other members of the Haynes staff, last year formed the Elmer Motor Corporation and apparently acquired the plant of the embarrassed Elkhart Motor Car Co., in Elkhart, Ind., has changed his base of operations to Cleveland, Ohio, where he has formed the Grant Car Co. Elmer is president and general manager.

The company purposes manufacturing what will be styled the Grant Six, which is the same six-cylinder model, designed by Charles E. Lohr, which it was intended to produce in Elkhart. Lohr, H. H. Murden, J. S. Worthington and E. W. Lawrence, all of whom were associated with Elmer in the Elkhart venture, comprise the engineering staff of the Cleveland concern.

The Elkhart property appears never to have come into the possession of the Elmer Auto Corporation. It was enmeshed in legal entanglements which, coupled with lack of capital, served to cause the Elkhart enterprise to be quietly abandoned.

Donaldson Joins Hands With Tracy.

Joseph Tracy, of New York, has taken unto himself a partner, who is no less than Henry F. Donaldson, president of the Society of Automobile Engineers. They will continue and enlarge the consulting engineering work performed by Tracy for several years, their field extending into research, development, design, construction, laboratory and road tests. For the present the headquarters in New York will be in the office already established by Tracy at 112 West 39th street. The Tracy testing laboratory in Rutherford, N. J., will be maintained as heretofore.

MacDonald Fails to Secure Injunction.

Judge Platt, sitting in the United States District Court in Hartford, has denied the motion for a temporary injunction made by John N. McDonald, of Weathersfield, Conn., seeking to restrain the Post & Lester Co., of Hartford, from alleged infringement of the MacDonald patent covering a tire chain repair tool. In dismissing the motion, Judge Platt directed that the case be proceeded with in the usual way.

OLD TRADESMEN IN NEW PLACES

Some Resign and Many Climb to Higher Positions—Transfers Reported from All Parts of the Country.

George I. Pound has been appointed general eastern sales manager for the Rowe Motor Truck Co., of Coatesville, Pa. Temporarily he will make his headquarters at 327 East 84th street, New York.

George Weber has been appointed factory manager for the Metzger Motor Car Co., of Detroit. He has had wide experience in the same capacity with the Locomobile, Buick and Waltham companies.

J. Arthur Hoffman, who for more than three years has had charge of the Studebaker Corporation's engineering board, has relinquished that position and retired from the automobile industry. He will engage in the real estate business for himself in Detroit.

John F. Toole, manager of the F. B. Stearns Co.'s branch in Atlanta, Ga., has been promoted to the management of the Stearns Pacific Coast branch in San Francisco. He succeeds A. S. Holden, who resigned in order to return to his home in Cleveland.

W. T. Wiggins, formerly an auditor for the Studebaker Corporation, has been appointed manager of the Studebaker branch in Portland, Ore. He succeeds Lloyd F. Weaver, who has been transferred to the management of the Studebaker branch in San Francisco.

Jasper Ewing Brady, who formerly represented the Ohio Motor Car Co. in the territory adjacent to Kansas City, has been transferred to Chicago, where he has assumed the title of district manager. The interests of the Ohio car in Kansas City and thereabouts have been taken over by the recently organized Ohio Motor Sales Co., of Missouri.

A. F. B. Klein, formerly manager of the Baker Electric branch in Chicago, has resigned that office to become manager for the Ohio Motor Car Co. in Chicago. He will have charge of the Ohio branch and garage, which will be opened May 1st at Michigan avenue and 21st street, and which will replace the temporary headquarters at 1523 Wabash avenue.

C. G. Wilson, who only recently was appointed manager of the Midland Motor Car Co.'s Chicago branch, has been called to the factory at Moline, where he has assumed the sales management of the company. Arthur H. Sackett, who has been identified with the Stevens-Duryea interests in Chicago, has succeeded Wilson as manager of the Midland branch in that city.

To fill the vacancies caused by the retirement of C. C. Hildebrand as assistant general manager and sales manager of the Chalmers Motor Co., of Detroit, H. W. Ford, secretary and advertising manager of the company, has been promoted to the first named office, and Percy Owen has been brought from New York to fill the post of sales manager. Like Hugh Chalmers himself, Ford is a graduate from the National Cash Register Co., while Owen has been identified with the automobile industry since its teething period. He is a genuine member of the old guard of the trade, and latterly has been sales manager for Carl H. Page & Co., the Chalmers agents in New York.

American Tire Treads for Europe.

A. A. Hedinger, until recently Boston manager for the J. M. Shock Absorber Co., has been appointed European representative of the Leather Tire Goods Co., of Niagara Falls, N. Y., and already has sailed for London with a stock of that company's Woodworth tire treads. He will carry a supply in London, and will also have an office on the Continent, where agencies will be established and where it is not unlikely a factory will ultimately be located. Most of Hedinger's work will be performed in Continental Europe, as the Woodworth tread agency in Great Britain already is in the hands of Morris, Russell & Co., of London. Until last year Hedinger, who is a native of Switzerland, handled American typewriters in Europe, which implies that he knows the territory which he will cover and the conditions he will encounter.

Company Built Around the Goby Engine.

The Goby Engine Co., which has been in process of organization in Cleveland, Ohio, for some time and which purposes building a sliding valve engine invented by C. S. Goby, which is reported to be something of a marvel, has completed its organization by electing Christian Girl, president; John D. Hull, of the Perfection Spring Co., vice-president; Ernest W. Farr, treasurer, and P. A. Connolly, secretary. The company, which is capitalized at $100,000, will build the Goby engine for the trade, and may license automobile manufacturers to make their own motors.

To Build Bodies for Canadian Trade.

Backed by several Detroit men, the National Body Co., Ltd., has been organized in Windsor, Ont., which is directly opposite Detroit, and will manufacture automobile bodies for the Canadian trade. A three-acre site has been secured, on which will be erected a two-story brick factory, 300x55 feet. The company will incorporate with a capital of $100,000.

To Double Output of Rawhide Gears.

The New Process Rawhide Co., manufacturer of rawhide gears, is about to make contracts for the enlargement of its plant in Syracuse, N. Y., which will just about double its capacity. The enlargement will comprise a four-story building, 125x66 feet, and a two-story addition to the present two-story factory.

Digitized by Google

BIG TAXICAB DEAL CONSUMMATED

New York's Largest Companies, Both Anxious to Sell, Finally Strike a Bargain—One Retains Bus Line.

The stockholders of the New York Transportation Co., the biggest taxicab operating concern in New York City, at a special meeting held in Jersey City on Tuesday, 26th inst., formally ratified the sale of the company's taxicab business and good will to the Connecticut Cab Co., and by the terms of the sale the latter company will take over the business and move into the quarters of the New York Transportation Co., at 49th street and Eighth avenue, on June 1st, next. The price paid for the 600-odd cabs, the equipment and the plant was not made public, but it is understood that it was a reasonable one. The New York Transportation Co. hereafter will devote its principal energies to the Fifth Avenue Coach Co., which it owns, and the scope of which, it is said, will be considerably enlarged in the near future.

The sale of the New York Transportation Co.'s taxicab business scarcely comes as a surprise. It has been known for some time that the company was desirous of disposing of it, though it was not until recently that matters were brought to a head. Similarly, it was rumored that the Connecticut Cab Co. was anxious to dispose of its holdings because of the small return on the investment. By taking over the cabs and business of the New York Transportation Co., however, it is hoped to reduce the ratio of overhead expense to profit and that the enlarged business will show a greater average return on the investment than did the smaller one. Whether the arrangement will have any effect on the rates of fare is a matter for the future to bring forth though it is said that "ultimately the fares may be reduced." In the meantime the Connecticut company's rates, which are 20 per cent. higher than the New York Transportation Co.'s, will be extended to the newly acquired equipment.

"A" Makes Use of Well-Known Names.

For a brief period it appeared that the peculiarly titled "A" Automobile Mfg. Co., of Sacramento, Cal., which for a year or more possessed an option on a factory site in that city, a picture of a large and uncommonly handsome automobile factory and plans for a motor car, had attained real importance. It was given out in California last week that R. A. Palmer, formerly general manager of the Cartercar Co., of Pontiac, Mich., and C. A. Trask, formerly superintendent of the same company, together with W. J. Mead, of the General Motors Co., had become interested in the "A" project and the information served to make it loom larger on the trade horizon. Unfortunately, however, Trask is now in Europe, and Palmer absolutely denies that he is or ever was interested in any way, shape or form in the California promotion. A representative of the latter concern was recently in Detroit, and at that time approached Palmer with a view of having him produce the chassis for the proposed California car, but Palmer prompty put aside the temptation. The report of his connection with it undoubtedly grew out of that circumstance.

Carter Corporation Formally Bankrupt.

After untying several legal knots, the court has formally adjudged the Carter Motor Car Corporation, of Washington, D. C., a bankrupt, the adjudication providing that the equity proceeding in Maryland, where the factory is located, shall not be interfered with. A. Gary Carter, president of the bankrupt concern, was also relieved as one of the receivers, Lucas P. Lowell being appointed to fill the vacancy. He will act as co-receiver with Wilton J. Lambert, and they will dispose of the assets of the company by order of the court. Meanwhile Gary A. Carter, as stated in last week's Motor World, has formed the Washington Motor Car Corporation, with himself as president, which company purposes operating the factory at Hyattsville, Md., and continuing the business.

Four Buildings for Ford on Coast.

After having spent considerable time on the Pacific Coast, James Couzens, secretary and treasurer of the Ford Motor Co., has returned to Detroit, after having perfected arrangements for the erection of four buildings which the Ford company will maintain in that part of the country. Since his return he has authoritatively stated that the four buildings will be located, respectively, in Los Angeles, San Francisco, Portland and Seattle, which statement settles some doubts which existed on that score, particularly as relating to the erection of at least two of the buildings. The structures will be of reinforced concrete, and under one roof will be housed salesrooms, service stations, storage quarters and an assembling plant, the cost of the four establishments representing an investment of approximately $1,000,000.

More Capital for Invincible Starter.

The Invincible Starter Co., of Detroit, which makes the acetylene starter of that name, has increased its capital stock to $25,000 and eletced new officers, as follows: Edward J. Corbett, president; D. W. Reinohl, vice-president; George S. Anderson, treasurer, and H. J. Weeks, secretary and general manager. In addition to Messrs. Corbett and Reinohl, the directors are Walter E. Oxtoby and George F. Monaghan. The company has increased its production until now it is turning out between 75 and 100 starters daily. Incidentally, the Invincible starter has been adopted by the United States Motor Co as standard equipment.

U. S. MOTOR INCREASES EARNINGS

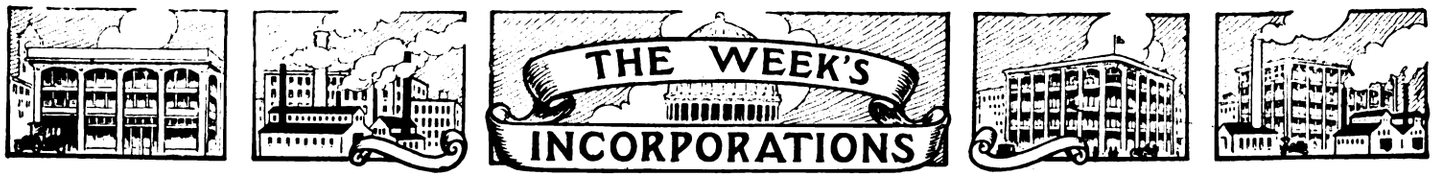
Six Months' Sales $1,000,000 Better Than Corresponding Period of Last Year—Briscoe on Selling Seasons.

According to a statement issued late last week by Benjamin Briscoe, president of the United States Motor Co., the sales of that big corporation's six automobile manfacturing plants—Maxwell, Columbia, Dayton, Brush and Alden-Sampson—for the six months, August, 1911, to January, 1912, inclusive, were $9,045,631.46, as compared with $8,042,920 for the corresponding period of the previous year.

These figures do not include the business of the Briscoe Mfg. Co., the Providence Engineering Co. or the Gray Motor Co.

The sales of the three latter companies for the six-month periods were $1,286,456.26 and $1,083,179.14, respectively. The profits from the operations of the United States Motor Co. and its manufacturing branches for the six months ending January 31, 1912, were $715,059.16.

"The financial condition of the company is showing constant improvement," said President Briscoe, "and while inventories are still necessarily large, the management of the company believes that their plans, involving a decided reduction of inventories and receivables, will be effected before the end of the fiscal year to an extent that will permit the company to go into the coming fiscal year with practically no floating debt.



"The automobile business is subject greatly to weather conditions, and is seasonable in the respect that about one-third of the business is done in the first six months of the fiscal year, and two-thirds in the last six months. The experience of the companies comprising the United States Motor Company has shown that the profits on automobile manufacturing for the year's cycle of operation are developed about 33⅓ per cent. in the first six months and 66⅔ per cent. in the last six months.

"The prospects for the heavy selling months—April, May and June—are very bright. There are orders on hand now up to the capacities of the factories for the next 90 days, and if the present rate of sales through the company's selling branches and dealers is maintained the sales will exceed the company's capacity to manufacture. During the month of March the sales have been running at about $100,000 a day."

Maxwell Again Takes Up His Duties.

J. D. Maxwell, president of the Maxwell-Briscoe Motor Co., and vice-president of the United States Motor Co., who some six months ago relinquished his work—but not his offices—to take a long vacation, has resumed his duties. The long rest contributed greatly to his health.

Hartford, Conn.—Stoddard-Dayton Motor Co., under Connecticut laws, with $5,000 capital.

Lansing, Mich.—Cyclo Carburetter Co., under Michigan laws, with $4,000 capital; to manufacture carburetters.

Galesburg, Ill.—Taxi Livery Co., under Illinois laws, with $5,000 capital; to deal in automobile livery. Corporators — Fred Peterson, R. Moore, Charles Miller.

Syracuse, N. Y.—Bissell Garage, under New York laws, with $10,000 capital; to operate a garage. Corporators—William H. Bissell, Philip Manheim, Budd Walts.

Chicago, Ill.—Empire Auto Repair Co., under Illinois laws, with $4,000 capital; to repair automobiles. Corporators—Ezra T. Fidler, James Ahern, Burton C. Lindley.

Butte, Neb.—Butte Auto Co., under Nebraska laws, with $15,000 capital; to deal in automobiles. Corporators—Frank E. Couch, J. R. Beatley, R. V. Wilson, F. A. Putnam.

Fort Worth, Tex.—Motor Car Specialty Co., under Texas laws, with $5,000 capital; to deal in automobile supplies. Corporators—E. C. Gose, F. H. High, R. R. Gilliland.

Newark, N. J.—Weldon Roberts Rubber Co., under New Jersey laws, with $100,000 capital; to manufacture rubber goods. Corporators—W. Roberts, P. F. Campbell, A. H. Sonn, all of Newark.

Cleveland, Ohio—Bingham Motor Car Co., under Ohio laws, with $10,000 capital; to deal in motor cars. Corporators—Herbert Bingham, C. N. Fiscus, C. F. Schrod, E. E. Thomas, William H. Gillie.

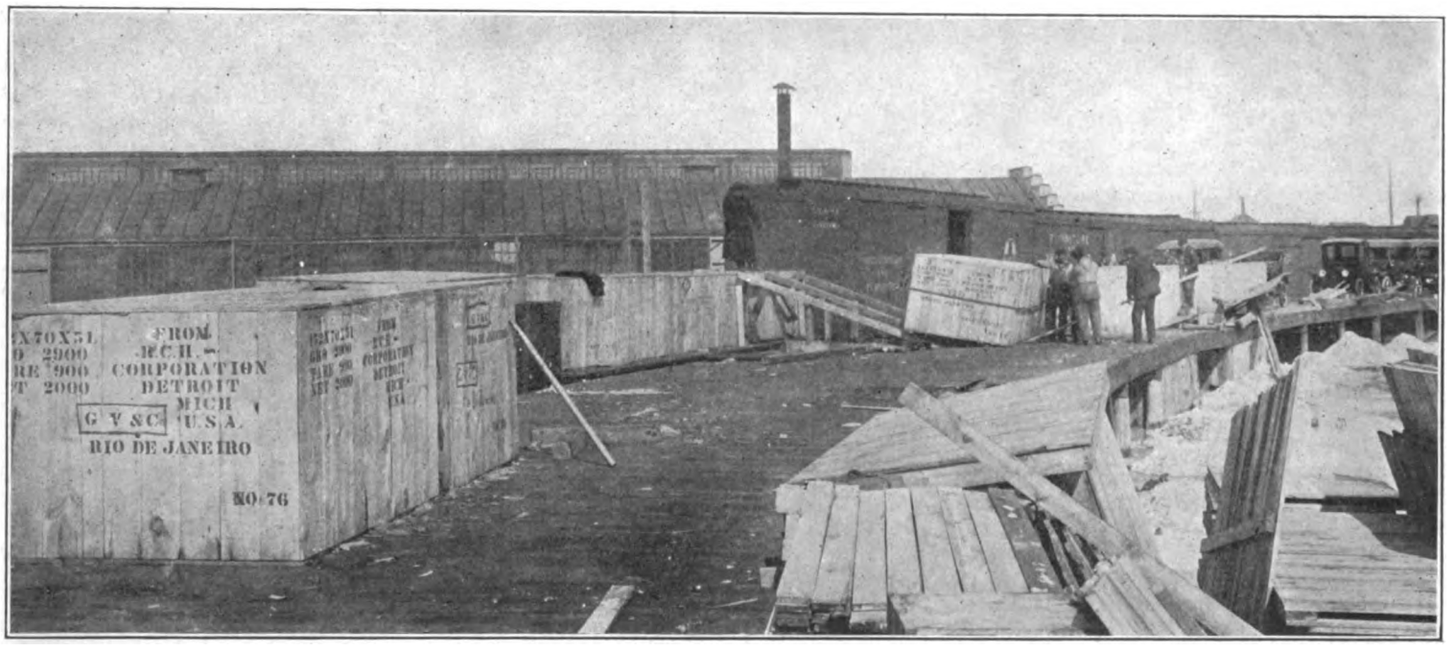
San Francisco, Cal.—Goodyear Tire and Rubber Co. of California, under California laws, with $100,000 capital; to deal in automobile tires, etc. Corporators—N. B. Taylor, E. Linkenfelder, J. F. Wise.

Toledo, Ohio—Erie Supply Co., under Ohio laws, with $10,000 capital; to deal in automobile supplies. Corporators—William J. Fritsche, Fred H. Kruse, Jennie Sansen, F. A. Brown and Mark Winchester.

New Brunswick, N. J.—New Brunswick Garage Co., under New Jersey laws, with $25,000 capital; to operate automobile garages. Corporators—J. Weigel, Jr., O. F. Bentell, W. Silzer, all of New Brunswick.

Akron, Ohio—Akron Motor Washer Co., under Ohio laws, with $10,000 capital; to manufacture automobile washing machines. Corporators—John Bauer, C. W. Sieber, M. F. Wolf, Joseph B. Sieber and M. Bauer.

Youngstown, Ohio — Motor Necessities Co., under Ohio laws, with $10,000 capital; to deal in automobile sundries. Corporators—L. H. Black, Chas. T. Gaither, Oscar G. Deibel, C. A. Manchester, L. A. Manchester.



Canadaigua, N. Y.—William J. Hawley Automobile Co., under New York laws, with $30,000 capital; to deal in motor vehicles and supplies. Corporators—Edson T. Case, William J. Hawley, Lincoln H. Hawley, all of Canandaigua.

Onondaga Hill, N. Y.—Boyle Bros. & Pate Co., under New York laws, with $5,000 capital; to conduct a general automobile selling and repairing business. Corporators—William D. Boyle, Jesse R. Boyle and Albert N. Pate, all of Syracuse.

New York, N. Y.—Market and Harlem Auto Trucking Co., under New York laws, with $10,000 capital; to operate an automobile delivery. Corporators — Burgess Osterhout, 633 West 115th street; James L. Robinson, 309 Lafayette avenue, Brooklyn; William Eastman, Roslyn, N. Y.

New York, N. Y.—Pierce, Wells & Keedwell Co., under New York laws, with $10,000 capital; to deal in motors, automobiles, etc. Corporators—Peter Krudler, Jr., the Bronx; Albert C. Keedwell and Albert D. Keedewll, both of 171 West 80th street.

Brooklyn, N. Y.—Alpha Rim Co., under New York laws, with $100,000 capital; to manufacture automobile rims, tires and supplies. Corporators—Clarence M. O'Donnell, 301 St. Nicholas avenue, New York City; George H. Tice, 480 16th street, and Max P. Bau, 197 Norman avenue.

SHIPPING PLATFORM AT R. C. H. FACTORY IN DETROIT SHOWING CARS BOXED FOR EXPORT

Digitized by Google

Robert Craig and Harry Bellamy have established a garage in Manchester, Conn.

G. P. Rothenberger & Son have opened a garage at 626 Superior street, Antigo, Wis.

Chappell Foote has opened a salesroom in Topeka, Kan. He has the agency for Cino cars.

Aaron Cohen and F. M. Zimmerman are preparing to open a salesroom in New Britain, Conn.

Carter & Hanson have purchased the garage formerly operated by Steve Davis in Dalton, Neb.

M. S. Van Eaton and A. J. Smith have formed a partnership and opened a garage at Pisgah, Iowa.

Milo Ball has opened a garage in Highland, Kan., where he will show Mitchell and Overland cars.

Henry Vogel and Frank McCord have formed a partnership and opened a garage in Carrington, N. D.

Carl Hagenson has sold his garage in Brown Valley, Minn., to H. J. Strasburg and Granville F. Rollins.

Dudley V. Haddock has purchased the interest of Byrd Latham in the Lewis Garage, St. Petersburg, Fla.

The Wilkes & Russell Garage in Massena, N. Y., has changed hands. Howard C. Munsen is the new owner.

A. R. Mayer has leased the garage and salesroom of the F. E. Walsh Garage on Eighth street, Milwaukee, Wis.

William Tweed has purchased the garage in Binford, N. D., owned by Edward Johnson and O. S. Broadshaugh.

Charles H. Duryea and William E. Sprague have formed a partnership and opened a garage in Babylon, L. I.

I. B. Ballard and I. N. Beeson have opened a garage at the corner of Monroe street and Sharp avenue, Spokane, Wash.

General Fred W. Green and Eugene Kerstetter have bought a lot on First street, Ionia, Mich., on which to erect a garage building.

The Tremaine Garage, at Phœnix, Ariz., has opened for business on West Washington street. Hudson and Mitchell cars will be dealt in.

The Central Automobile Supply Co. has established salesrooms at 310 Ninth street, Des Moines, Ia. A. W. Eggersten is president of the company.

I. M. Spoogle and E. S. Sauber have formed a partnership under the style Allen's Garage Co., and opened salesrooms and a garage at Chico, Cal.

W. D. Kenny, of Kansas City, has invaded Wichita, Kan., and opened salesrooms at 238 South Market street. He will handle Detroit Electric cars.

The Merwin Auto Sales and Repair Co. has taken over the Motor Mart Garage in Youngstown, Ohio, and will carry on a general garage and repair business.

C. Cassard Schroth, representative for the Stearns-Knight cars in Washington, D. C., has removed his salesrooms from 908 to 1608 Fourteenth street, N. W.

Twin Bridges, Mont., soon will boast of its first garage. G. F. White and T. W. Stalcup are remodeling the old Seyler building on Madison street for that purpose.

Gus D. Revol, the Cadillac agent at New Orleans, La., has transferred his store from Julia street to Automobile Row—which in this case means to 701 Baronne street.

The business of the Atlantic Garage at Grant City, N. Y., has been acquired by R. Jurgenson and Frank B. Killian. They will do business under the style the J. & K. Motor Car Co.

The Klemme Auto Co., of Davenport, Ia., has been taken over by a new company, the Union Auto Co., of which Louis Otto is president, R. H. Postel secretary, and George Thoen treasurer.

Arthur Soss has purchased the interest of L. Van Doren in the O Street Garage, Lincoln, Neb., and will continue the business alone. He has the agency for Maxwell, Cutting and Marathon cars.

The Hartford Suspension Co. has established a branch in Detroit at 801 Woodward avenue, of which M. L. Mathews is manager. A full stock of Truffault-Hartford shock absorbers will be carried.

The John Deere Plow Co., of Dallas, Tex., dealer in agricultural machinery, with branches all over the country, has added automobiles to its line. It will sell Abbott-Detroit cars throughout the Lone Star State.

Carroll A. Haines & Co., of Philadelphia, agents for Baker electrics, have added gasolene vehicles to their line and taken the agency for Herreshoff cars. Their salesrooms are at 2214 Spring Garden street.

Krueger Brothers, who have the largest tailoring establishment in Neodesha, Kan., have branched out into new fields and added automobiles to their suits and overcoats. They have taken the agency for Overland cars.

LeHardy & Lindsay, who handle the Marmon line at Rochester, N. Y., have found their salesroom too cramped and will move into more spacious quarters next month. Their new address will be 398 East avenue.

The Reed Motor Supply Co. has been organized with E. A. Reed as president, and headquarters at 80 West Seventh street, St. Paul, Minn., Reed formerly was a partner in the Electric Mfg. Co., 355 Minnesota street.

The New York Auto Exchange has opened salesrooms at the junction of Granby, Bute and Charlotte streets, Norfolk, Va. It will handle the R. C. H. and Case cars, as well as the White line of pleasure cars and trucks.

Universal motor trucks will be distributed in Chicago, Ill., by a direct factory branch which has just been opened at 2216 Michigan avenue. Charles Fisher, formerly sales manager of the Mais Motor Truck Co., is in charge.

Under the style of the Velie Auto Sales Co., a company has been organized in Waterville, Me., with headquarters at 24 Charles street, and E. T. Morton as manager. As the name indicates, Velie cars are to be featured.

Under the style the Batavia Tire Co., a tire supply store has been opened in Greenwich, Conn., under the management of Walter Scofield. It will be ready for business on April 1, and will make a specialty of Batavia tires.

Under the style the Marion-Garford Co., a new concern has been established in Boston, Mass., with headquarters at 1016 Commonwealth avenue, and F. F. Wentworth as manager. As the name indicates, Marion and Garford cars will be carried.

The Ford Motor Car Co., of Spokane, Wash., has moved from its old location at 1228 Sprague avenue to more commodious quarters at 1221 Riverside avenue. The old quarters in Sprague avenue will be occupied by the Abbott-Detroit Sales Co.

With the object of handling the Minnesota-made Luverne automobile, the Luverne Automobile Sales Co. has been organized in the Twin Cities. A. G. Bauer is the St. Paul manager, while E. F. Bauer will look after the Minneapolis salesroom.

The Steckel Motor Truck Co. has established salesrooms at 1414 Ridge avenue, Philadelphia, Pa., where Lincoln delivery wagons and B. O. E. trucks will be handled. Eastern Pennsylvania and southern New Jersey are included in the concern's territory.

Under the style of Graham & Seizer a

Digitized by Google

new firm has been in formed in Peoria, Ill., to take over the business of M. M. Baker & Co., dealers in automobile and electrical supplies, at 625 Main street. R. F. Graham and L. M. Seizer comprise the new firm.

J. H. Van Brunt and William Bogen have formed the Selden-Maxwell Automobile Co. in St. Joseph, Mo., and opened a salesroom at the corner of Ninth and Francis streets. As the name indicates they will handle Selden and Maxwell pleasure cars, and Sampson trucks.

Heralded as one of the largest and best equipped supply houses in the West, the Arthur Storz Auto Supply Co. has commenced business at 2022 Farnam street, Omaha, Neb. Arthur C. Storz, Donald D. Troup and Hal M. Brady are the men composing the company.

The Connecticut headquarters for Atterbury trucks has been moved from the town of Meriden to 19 Hoadley place, Hartford, in the same State. Edward J. Ives is manager of the company, which will establish sub-agencies in New London, New Haven and Waterbury.

Clarence Naville, of Ambia, Ind., has taken over the interest of J. Bryant in the firm of Bryant & Holloway, who operate a garage at 210 Columbia street, Lafayette, Ind. Simultaneously with the change of ownership the name of the company has been changed to Holloway & Naville.

A voluntary petition in bankruptcy has been filed by the Auto and Motor Boat Co., of 801 Capitol avenue, Houston, Tex. Its liabilities are $22,388.13 and its assets $8,456.79, the latter consisting of $5,372.29 in open accounts and two second-hand automobiles. More than 60 creditors are listed in the schedules.

Dugger & Willis have purchased the entire business and good-will of the Mount Pleasant Auto Machine Co., which conducted a foundry, repair shop and garage in the Tennessee town of that name. They will continue the foundry and repair departments, but will abandon the garage, as that has proved unprofitable.

For a consideration of $50,000, W. P. B. Campbell has sold the Parker Garage, at 45 South 10th street, Minneapolis, Minn., to John McKnight. The sale only involves the real estate and building, the agency of the Lozier and Marmon lines being continued by Campbell in the old quarters under a lease agreement.

Because H. DeWilde has retired from the Wallace-DeWilde Co., of Newark, N. J., distributor of Cole cars in Hudson and Essex counties, New Jersey, the name of the company has been changed to the Wallace Motor Car Co., with Henry A. O'Brien as president; John B. Wallace, treasurer, and J. H. Bawden, assistant sales manager.

Having found its present quarters too small, the Kline Kar Motor Co., of Pittsburgh, Pa., of which J. D. Kerr is manager, has let contracts for the erection of a modern fireproof building on the Boulevard in that city. It will have a frontage of 80 feet, with a white and blue face, and will contain all conveniences. It will cost approximately $30,000.

William M. Botto, who was vice-president of both the Abbott Motor Co. and the Regal Sales Co., agents for Abbott and Regal cars, respectively, in New York City, has sold out his interests in both companies and become affiliated with a new company which will devote its energies to the sale of Imperial and Havers cars. The new company is practically a reorganization of the Detmar Auto Sales Co., in which Fred C. Robie, formerly of the Excelsior Supply Co., of Chicago, and Albert L. Kull, another old-timer, remain. The quarters of the Detmar Auto Sales Co., at 1662 Broadway, will be retained.

Recent Losses by Fire.

Erie, Pa.—Lambert's Garage, 714 Myrtle street, burned, and eight cars damaged. Loss, on building alone, $1,000.

Washington, D. C.—Terminal Taxicab Co.'s repair shops, 1231 Twentieth street, and six cars destroyed. Total loss, $11,500.

Westerly, R. I.—Westerly Garage, corner Main and Union streets, and five cars destroyed. Loss, $10,000, covered by insurance.

Maple Glenn, Pa.—George Lenhart's body building plant and paint shops and seven automobiles destroyed. Loss, $40,000, partially insured.

Pittsburgh, Pa.—Oakland Automobile Co.'s garage, 3417 Forbes street, damaged by fire for the second time in two weeks. Building and sixteen cars ruined. Loss, $41,000.

Chicago, Ill.—Grand Boulevard Automobile Garage Co. and Stoddard-Dayton Garage, at 43d street and Grand boulevard, with 27 automobiles, destroyed. Estimated loss, $100,000.

Atlas Appeals from Weed Injunction.

On Thursday last, 21st inst., the Atlas Chain Co., of Brooklyn, N. Y., filed an appeal which seeks to stay the preliminary injunction obtained by the Weed Chain Tire Grip Co., of New York, for infringement of the Parsons tire grip patent. The inujnction was granted to the Weed people on presentation of evidence which tended to show that the Atlas chain, while fitting closely the tread of the tire, yet crept slowly, and thereby constituted an infringement of the Parsons patent.

Jury Fixes Damages Panhard Must Pay.

After a trial lasting more than four days, the jury sitting in the United States District Court for the Southern District of New York, on Wednesday, 20th inst, rendered a verdict in favor of the Interborough News Delivery Co. in its suit for $6,663 damages against Panhard & Levassor. The amount of the judgment, however, was reduced to $1,768, this sum representing the damages which, in the opinion of the jury, the News company suffered by reason of the condition of the wagons sold to it by the Panhard people. These wagons did not perform well, and it was charged that they were not 1910 models, as specified in the contract, but contained power plants of older vintage.

Gets Hupmobile Agency for Bulgaria.

H. G. Nergararian, a Bulgarian, who once was in the Oriental rug business in Detroit and who returned to his native country, where he sold agricultural machinery, again has changed his sphere and embarked in the automobile business. He recently visited Detroit, where he secured the Hupmobile agency for several Bulgarian and Roumanian provinces. He will make his headquarters at Varna, Bulgaria.

Indianan "Prospecting" in Kansas.

A. Afander, who is described as a mechanical engineer and designer of Peru, Ind., is reported to be in communication with a commercial club of Hutchinson, Kan., with a view to acquiring the old Sellers automobile plant in that city. Afander has informed the Kansans that he and his associates will pay them a visit and locate an automobile factory "in their midst."

Another American Car Gets Into Japan.

Sale & Frazar, Ltd., an important firm of importers located in Tokyo, who handle American locomotives and the products of the United States Steel Corporation, have enlarged their operations by taking on automobiles. They have secured the Packard agency for Japan, Korea and Manchuria, in which countries they believe there is a considerable market for six-cylinder cars among the nobility.

Randall-Faichney to Build in Boston.

The Randall-Faichney Co., of Boston, which manufactures the Jericho horn, B-line grease guns and other specialties, has let contracts for a concrete factory on Atherton street, near Boylston Station, which is in the West Roxbury district of Boston. The structure will be of four stories, 60x250 feet. It will be occupied jointly by Randall-Faichney, MacKae Mfg. Co. and the Babson-Dow Co.

Krit's President to Make Wide Sweep.

Lawrence Moore, president of the Krit Motor Car Co., of Detroit, has departed for an extended trip, which will include the South, Southwest and Pacific Coast; it will occupy a month or more.

Jackson to Get a Crankshaft Plant.

The Hastings Motor Shaft Co., of Hastings, Mich., is making ready to move to Jackson, in the same State. The company manufactures crankshafts, camshafts, etc.

NEW YORK, MARCH 28, 1912.

THE MOTOR TRUCK THAT IS STILL LACKING.

It is generally admitted that the motor truck is at its best on long haul work, in which its speed, as compared with that of horses, appears to the best advantage, and its freedom from the effects of fatigue is of the greatest value. Conversely, the motor truck works under the most unfavorable conditions for economical operation when it makes short hauls and stands idle a large proportion of the time on account of delays due to loading and unloading and the like. The distances being short, there is little or no opportunity to utilize the superior speed of which the machine is capable, not because of the machine does not move rapidly when under way, but because the running time is so short as compared with the idle time that the gain is of little practical value. Nevertheless, the fixed charges on the truck remain unchanged and the wear and tear due to frequent stops and starts is approximately equal to that entailed by long runs—more in some cases and less in others. Consequently it costs almost as much to operate a motor truck under these conditions as on long haul work, the only difference being in fuel and oil consumption.

Horses, on the other hand, are at their best when the trips are short and the idle time aggregates a considerable proportion of the day, for they have plenty of rest and thus are enabled to do their best work while on the road. Horses stand up very well under such work, the wear and tear, so to speak, being quite low; whereas on long haul work they not only are necessarily slow, but the protracted exertion entailed by a very hard pull renders a horse unfit for further work until thoroughly rested.

Apparently, then, the horse is at its best on short haul work and the motor truck at its worst, and while there undoubtedly are many motor trucks doing good short distance work, there is an enormous field for a machine that is specially adapted to compete with the horse under conditions that are wholly favorable to the animal. It would seem that this phase of the business has not been given the attention it deserves, and that there is a great field that is practically uncultivated.

As the whole thing resolves itself into a matter of dollars and cents, the solution of the problem clearly is in the designing of a truck that can be operated at a minimum cost. And while it is of course very much easier to suggest that such a thing be done than it is to bring about its accomplishment, it may be pointed out that for short haul work no great speed is required and that less speed means less power, with a corresponding reduction in the expense of operation, of upkeep and wear and tear, of tire cost and, in fact, nearly everything except the fixed charges—and even these would undergo some revision, for the first cost of the truck naturally would be less than that of a high powered machine and the depreciation and insurance would be correspondingly lower. There also is the possibility that a short-haul vehicle could be operated by a less expensive man than a long-distance machine.

It is undeniable that there is plenty of work for the motor truck to do in long distance hauling, and manufacturers as yet have little occasion to invade the last stronghold of the horse; but the fact remains that in order to completely emancipate the horse he must be beaten at his own game, and in order to do this it probably will be necessary for motor truck builders to specialize in machines that, while perhaps unsuited to long distance work, will operate as economically in their own particular field as the high-powered long distance cars do in theirs.

CENTERED CONTROL LEVERS AND TIRE IRONS.

Though the location of control levers in the center of the footboard is a laudable tendency toward increasing accessibility by permitting easy entrance to the driver's compartment from either side, not a little oversight of the possibilities of the construction is apparent on the part of some manufacturers. For instance, there is little sense in carefully designing for center control and then deliberately blocking one of the doors with spare tires. Still there is a very considerable number of manufacturers who do so. The remedy is plainly up to the manufacturer in the original location of the tire irons. Literally, there is no excuse for the carrying of spare tires on the running board other than custom; there are several other places which will serve as well for the purpose, though few manufacturers give evidence of the realization by finding other and better locations. Unfortunately it is necessary that spare tires be carried, but as long as they are carried their location is of little moment provided only that they do not defeat some other ends. At least one manufacturer has hit upon the very good scheme of providing a steel tire case below the body in the region of the rear axle, and the idea marks progress. A few others regularly place tire irons at the back of the body which is not an illogical place for them, though it would seem that there is room for ingenuity on the part of body builders in the designing of suitable compartments where tires may be stored, fully protected and completely out of sight.

NEW JERSEY IS FREED

Long Fight for Reciprocity Lost and Won Within Six Days—State Senate Reverses Itself—Governor's Approval Already Assured.

On Thursday last, 21st inst., New Jersey, by an 8 to 10 vote of its senate, elected to remain outside the Union for another year by defeating the automobile recoprocity bill which several weeks ago had been passed unanimously by the assembly.

Six days later, Wednesday, 27th inst., the spirit of reason dominated the same body and the senate reconsidered its previous action and, by a vote of 11 to 9, reversed itself, thereby enacting the Stickel bill, and, after a fight that has extended over a period of some five years, tore down the Chinese wall which the live but lamented "carpetbagger," Joseph Frelinghuysen, had erected around the State.

Credit for the reconsideration and the great victory achieved is due largely to Senator Colgate, who refused to be discouraged and to accept as final the adverse action of Thursday last. As victory required that but one senator change his vote, Colgate and his associates who favored the Stickel bill labored unremittingly to that end and finally converted and won over to the side of reason and reciprocity Senators Price and Silzer. Senator Barber, who favored the bill, was absent when the adverse vote was taken on Thursday last, but he was present yesterday and lined up with the majority. The other senators who voted to make their State an integral part of the Union were Messrs. Edge, Fielder, Johnson, Low, Pierce, Prince and Slocum.

Although Carpetbagger Frelinghuysen —who votes in New Jersey but spends most of his time in New York—is no longer a member of the senate, the narrow spirit of Frelinghuysenism was still strong enough to induce Senators Davis, Gaunt, Gebhardt, Hand, Leavitt, Lewis, Nichols, Read and Smalley to cast their ballots against the bill demolishing the Chinese wall. Senator Davis was present when the vote was taken last week, but he straddled the issue and declined to cast his ballot. Yesterday, however, he ranged himself with the opponents of reciprocity.

As Governor Wilson already is committed to the bill, that he will sign it is certain. When it is signed, and the measure becomes a law, non-residents will have the privilege of entering New Jersey without cost for 15 days of each year, while New Jersey motorists, for the first time in many years, will be enabled to visit the other States of the Union without let or hindrance, or special tags or special payments, such as the miserable law imposes on them wherever they go.

The bill carries with it a doubling of the license fees, but as most of the New Jersey automobilists have at nearly all time been ready to accede to an increase of the fees, that feature of the bill has not served to greatly hinder its passage. In the fight for the measure, all of the old familiar arguments were threshed and rethreshed, its opponents, as usual, refusing to see or admit that what is fair and good for all other States is fair and good for New Jersey.

Fisticuffs Follow San Jose Racemeet.

Excitement there was in plenty at the race meet held at the San Jose (Cal.) Driving Park on Sunday afternoon, March 17th, under the auspices of Emile Agraz and W. T. Buehren.

The excitement, however, was not all of the sort which naturally crops out during motor speed contests. Not a little of it was stirred up by the presence of a bad water hole in the backstretch of the track, and the water and mud and spray which emanated therefrom as each of the contending cars dashed across the wet spot added somewhat to the spectacle, and a great deal to the dangers of the drivers, so much so that Weldick, driving a Mitchell car, dropped out of two events, and Jeffkins, in a Buick, out of one, both being temporarily blinded by the muddy water. The most excitement, however, was caused after the racing terminated and took the form of an unannounced fistic encounter between two of the drivers, Agraz and Jeffkins. The Maxwell driver accused his Buick colleague of having "bumped" him on one round of the last event of the day, the 25-mile free-for-all. During the encounter which followed Jeffkins and Agraz were floored successively.

The track honors were about equally divided between Earl Cooper, who piloted the Stutz car and won both the three-cornered match race over a distance of five miles in 5:2 and the 25-mile free-for-all, in which he covered the distance in 25:18, and Earl Devore, whose hand guided the Buick stock car which won the five-mile stock car race in 5:21 and the 10-mile race for cars of 30 horse power in 10:40⅗. In only one event was the average speed better than a mile-a-minute gait. This was in the first event—one mile, flying start, against time—which was won by Jeffkins in 55⅕ seconds, at a speed of 65.2 miles per hour. Summary:

One mile, against time, flying start—Won by R. Jeffkins (Buick); second, Earl Cooper (Stutz); third, Harold Hall (Comet). Time, 55⅕.

Five miles, stock cars—Won by Earl Devore (Buick); second, Emile Agraz (Maxwell); third, Robert Buehren (Sunset). Time, 5:21.

Five miles, three-cornered match—Won by Earl Cooper (Stutz); second, Harold Hall (Comet); third, Jeffkins (Buick). Time, 5:02.

Ten miles, 30 horsepower cars—Won by Earl Devore (Buick); second, Emile Agraz (Maxwell); third, Fay Cooper (Comet). Time, 10:40⅗.

Twenty-five miles, free-for-all—Won by Earl Cooper (Stutz); second, Harold Hall (Comet); third, Emile Agraz (Maxwell). Time, 25:18.

April 29-May 4, Burlington, Vt. — Burlington Merchants' Protective Association's annual show in State Armory.

May 4, Santa Monica, Cal. — Santa Monica road race.

May 14-17, Chicago, Ill.—Chicago Motor Club's reliability run for commercial vehicles.

May 30, Indianapolis, Ind.—Five hundred miles International Sweepstakes race on the speedway.

May 30, Salem, N. H. — Rockingham Park track races.

June 20, Chicago, Ill.—Chicago Motor Club's annual hall climbing contest on Algonquin Hill.

Clever Scamp Victimizes Chauffeurs.

After "hiring" a number of chauffeurs to run his imaginary car, and filching them out of "security" ranging from $100 to $500 each, George L. Lewis, of Locust Valley, L. I., finally ran into a trap set for his special benefit, and was placed under arrest early this week. The case against him was so strong and conclusive that he was glad to be allowed to plead guilty to petty larceny.

According to the testimony, Lewis had advertised for a chauffeur, saying that he desired the services of an experienced man to run an automobile at $22 a week. Maurice Hogan, of 260 West Sixteenth street, New York City, answered the advertisement, and upon meeting Lewis was taken to a garage uptown, where he was shown an Alco car. Lewis also told Hogan that he would have every night off, and took him to a tailor's, where he was measured for a complete chauffeur's outfit. Lewis then said that Hogan must give $500 security before he would employ him. Hogan did so, and the next day went to visit Lewis at the Continental Hotel, where he was informed that Lewis had left, giving them a worthless check in payment for his board. Hogan then went to the garage, where he was informed that the automobile did not belong to Lewis.

Hogan next carried his tale of woe to the district-attorney, and, several similar complaints reaching the latter's office at the same time, detectives were commissioned to answer ads that resembled the one which attracted Hogan. As a result they caught Lewis in short order.

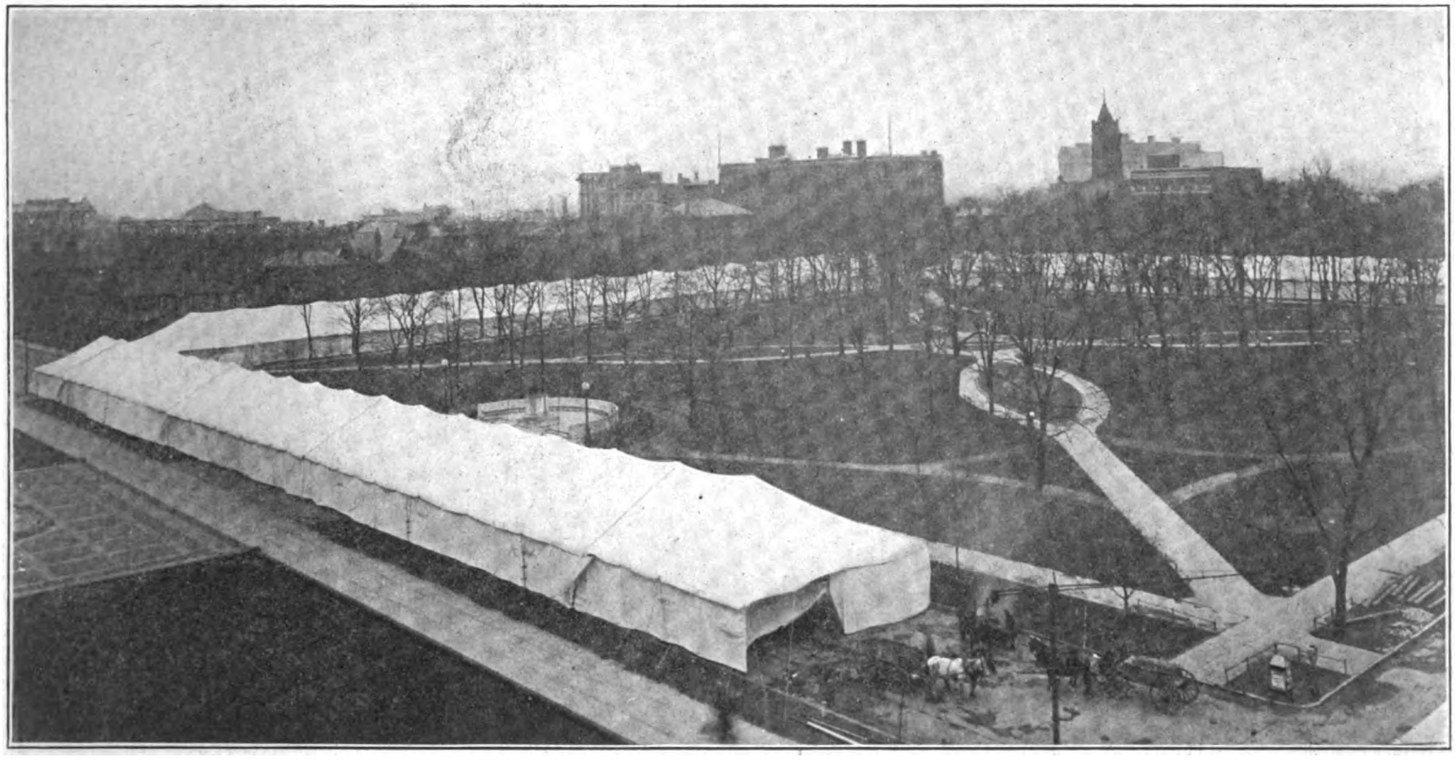
INDIANAPOLIS'S TENTED SHOW

Hoosiers Make Brave Display Amid Most Unusual Surroundings—City Park and Sidewalks Supply Setting.



After having tried the "open house" show, the term serving to signify that individual dealers decorated their individual showrooms and kept "open house" for a week for the edification of those who cared to stroll in and inspect the newer models on view, Indianapolis at last has a sure-enough show, housed all under one roof, and it is a show that it is unusual in more than one respect; it was opened on Saturday night, 20th inst., under the auspices of the Indianapolis Automobile Trade Association, and will finish its run on Saturday night, 30th inst.

In the first place, the show bears the distinction of being the first event of its kind to be held literally out on the streets of the city; incidentally, it is the first real show that Indianapolis ever has had, despite the fact that the Indiana city is notable for the number of automobile and accessory manufacturers located just within or just without its limits. As there was no building available which would serve to house all the exhibits without cranping, the promoters hit upon the novel scheme of roofing over a public park with canvas—converting University Park into an immense tenting ground pro tem. Around three sides of the park, the sidewalks and pavements serving as the floor, are ranged the wares of some 72 exhibitors, including 51 varieties of pleasure cars, 13 makes of trucks and almost literally a carload of accessories, to say nothing of nine brands of motorcycles.

Despite the difficulties under which the decorators labored, a more than ordinarily pleasing effect was obtained with the help of strings of incandescent lights of different colors, festoons of laurel and colored bunting stretched from the roof down to the sides, and a plenitude of large American flags draped over the tent poles. Music is furnished by three orchestras, one to each of the three sections of the big exhibition tent. Though on Saturday Indianapolis was visited by a severe rainstorm and on Monday there was almost a foot of snow on the ground, crowds flocked to the show, and, contrary to pessimistic expectations, the canvas roof proved itself impregnable and the inclement weather was kept outside.

Among the 200-odd pleasure cars on view, but a single newcomer put in an appearance. It is the Empire, which is the product of the Empire Automobile Co., of Indianapolis, successor of the Empire Motor Car Co., the previous producer of the car. Though it was the original intention of the company to produce two models, a "20" and a "25," production was centered on the "20," which is shown in both roadster and touring car forms. As the designation of the car indicates, the motor is of 20 horse-power and has four cylinders cast in a single block, and measuring 3½x4½ inches bore and stroke, respectively. The other essential features of the car include multiple disk clutch, three-speed selectively operated change gear mechanism, with a single lever placed in the center of the footboard for control, semi-floating rear axles and 104-inch wheelbase. The chassis is mounted on semi-elliptic springs in the front and three-quarter elliptic springs in the rear; front and rear wheels are shod with 32 x 3 and 32 x 3½ inch tires, respectively, and the list price includes such items of equipment as lamps, tools, tire repair kit, horn and jack.

Of the other exhibitors, those who show pleasure cars are: The American Sales Co., American; Archey-Atkins Co., Pierce-Arrow, Hudson, Detroit electric; Conduitt Auto Co., Peerless, Knox; Capitol Garage Co., Lion; Buick Motor Co., Buick; J. I. Case Co., Case; Cadillac Auto Co., Cadillac; Fisher-Gibson Co., Overland, Stoddard-Dayton, Stearns-Knight, Everitt, Brush; Finch-Freeman Auto Co., Marathon, DeTamble; Ford Motor Car Co., Ford; Frank P. Fox, Pope-Hartford; Hearsey-Willis Co., Hupmobile, Mitchell; Henderson Motor Sales Co., Cole; Haynes Automobile Co., Haynes; Indiana Auto Co., Chalmers, Reo; Ideal Motor Car Co., Stutz; Auburn Motor Co., Auburn; Empire Auto Co., Empire; Baker Electric Sales Co., Baker; Motor Car Mfg. Co., Pathfinder; Merchants' Electric Auto Co., Wescott, Woods; McFarlan Six Sales Co., McFarlan; Nordyke & Marmon Co., Marmon; National Motor Sales Co., National; O. B. Jameson, Staver-Chicago; Oakland Motor Co., Oakland; Premier Motor Sales Co., Premier; Rinne-Pfaff Co., Lambert;

Frank Staley Co., R. C. H.; Studebaker Corporation, E-M-F, Flanders; Sterling Motor Car Co., Paige-Detroit, Firestone-Columbus; State Auto Co., Marion, Krit; United Motors Co., Columbia-Knight, Maxwell; Waverley Co., Waverley; Walker Electric Co., Walker; Pilot Motor Car Co., Pilot.

Commercial vehicles were exhibited by: Buick Motor Co., Buick truck; Carr's Auto Place, Little Giant; Finch-Freeman Auto Co., Service; Avery Co., Avery; International Harvester Co., I. H. C. truck; Auburn Motor Co., Auburn; Morton Place Auto Co., Dreadnought-Moline; Merchants' Electric Auto Co., General Motors Co. truck, Kelly; McFarlan Six Sales Co., Whitesides; Mais Motor Truck Co., Mais; Premier Motor Sales Co., Premier; Walker Electric Co., Walker.

The exhibits of accessories and motorcycles are as follows: R. J. Irvin Co., bodies and tops; Hide, Leather and Belting Co., accessories; National Refining Co., lubricants; Auto Lighting and Electric Co., lighting systems; Acme Foundry Co., castings; Frank S. Feeser Co., lighting systems; Fisher-Gibson Co., accessories; Gates Mfg. Co., tops; B. E. Griffy Co., advertising novelties; Guarantee Tire and Rubber Co., accessories; Haywood Tire and Equipment Co., vulcanizing outfits; Hearsey-Willis Co., accessories; Henry Mfg. and Grease Cup Co., grease cups; International Metal Polish Co., metal polish; Indianapolis Auto Top and Rubber Tire Co., tops and wind shields; General Oil Works, lubricants; Electric Light and Starter Co., starters; Indianapolis Brass Co., brass goods; Motor Starter Co., self-starters; Motor Accessories Co., accessories; Charles H. Moore Co., lubricants; Irvin Robbins Co., bodies; Pumpelly Battery Co., batteries; Wyoming Lubricating Spring Co., springs; Sanborn Electric Co., electrical supplies; Johns-Manville Co., electrical supplies; Merkel Motor Co., Merkel; H. L. Dipple, Harley-Davidson; George C. Detch Wheel Co., Reading Standard, Pierce and Pope; G. H. Westing Co., Indian; Gus Habich, Excelsior and Thor; Flanders Motorcycle Co., Flanders.

INTERIOR OF INDIANAPOLIS'S TENTED SHOW—ASPHALT SIDEWALKS SERVING AS SHOW SPACE AND AISLES

Knight Patents "Silent" Connecting Rod.

Having succeeded in obtaining a silent valve mechanism, which later was supplemented by a patented "silent" piston, Charles Y. Knight has turned his attention to the silencing of other parts of his engine, and just has been allowed another British patent, No. 20,508, on a method of constructing connecting-rod big end bearings. The design of the new Knight is extremely simple, embracing the use of rings of some such substance as fiber between the "cheeks" of the crankshaft and the connecting rod bearings. The object aimed at is to prevent any noise being caused by endwise movement of the connecting-rod big end bearings on the crank pins.

Further Decline in French Exports.

Statistics just issued by the French government regarding the exports of motor cars during the first two months of 1912 do not hold much comfort for the French manufacturers. During those two months the decline which set in last year was continued, but $6,010,400 worth of automobiles being sold in other countries, as compared with $6,093, 000 in the same period of the preceding year, a loss of $82,600. Increases were registered in the shipments to Belgium, Germany, Switzerland, Austria, Spain and Algiers, while in all other countries decreases were recorded. Imports of foreign-made cars into France dropped from $425,800 in January-February, 1911, to $325,800 in the same period of 1912. Of all the automobile manufacturing countries the United States alone increased its shipments to France, the figures for the respective periods of 1911 and 1912 being $43,000 and $84,800—an increase of $41,800 or 97 per cent. The United Kingdom suffered a loss of nearly $70,000, while Germany recorded a decrease of $73,000, or more than 60 per cent. Belgium decreased its sales by $10,000.

PATENTEES AND THEIR RIGHTS OF MONOPOLY

Attorney Who Won the Famous and Much-Abused Mimeograph Case in United States Supreme Court Discusses the Subject and Points Out Why Complete Monopoly Is Proper and Not in Restraint of Trade—Wisdom of Controlling Certain Supplies.

It is so rare that an attorney who wins a case in the Supreme Court of the United States has reason for displeasure that Samuel Owen Edmonds, the member of the New York bar who successfully argued the now famous Dick mimeograph case before that tribunal, may be said to enjoy unique distinction. For despite his great victory, Counselor Edmonds is, if not unhappy, at least not thoroughly pleased. And not without reason; for not often has a decision of the highest court aroused such unmeasured criticism, if not condemnation.

The Dick case, as will be recalled, was decided by a divided vote of the Supreme Court, Chief Justice White writing an uncommonly vigorous dissenting opinion, his expressed fear of grave consequences that might follow the extension of monopolistic trends having been quoted and quite generally applauded throughout the length and breadth of the land, while, by the same token, the ruling of the majority of the court fairly has been lambasted. It is this lambasting—"abuse," Mr. Edmonds terms it—that has contributed to that gentleman's state of mind.

"The volume of ignorance that has been displayed, and the quantity and quality of the misstatements, or misconceptions, that have followed the decision are not short of astonishing," said Mr. Edmonds, who is attorney for the United States Motor Co., among other large concerns, in the course of a talk with a Motor World representative. "Most of the published criticism has grown out of the dissenting opinion of the Chief Justice and the two associates who agreed with him, their views having been printed broadcast while the opinion of the majority of the court appears not to have been generally read, or, if so, it has been but imperfectly digested. Had the prevailing opinion been given half the attention accorded the dissent, much that has been printed would have been left unsaid. The popular notion appears to be that the majority decision upholding the patent is revolutionary. As a matter of fact, it is nothing of the sort. It is in line with the rulings which have been made by the Circuit and Appellate Courts for many years. The law books fairly overflow with similar decisions; every lawyer is familiar with them, and the Dick case attracted general notice because it was the first time that the legal point involved reached the Supreme Court and in doing so brought a dissenting opinion from the Chief Justice himself. This legal point, which was sustained by a majority of the court, is really almost as simple as the alphabet itself. It merely upholds the right of a patentee to do with his invention whatsoever he pleases, and to enjoy for a term of 17 years the exclusive and far-reaching monopoly which is guaranteed by the Constitution of the United States."

"Carried to its logical conclusion," interrupted the Motor World representative, "is it not a fact that the Dick decision gives to a patentee not merely the right to control the manufacture, distribution and price of his invention; but, in the case of a gas engine, for instance, does it not enable him to specify the particular oil, spark plug or magneto which shall be used with the engine, and to require that they shall be purchased from a particular source, and does not such a condition make for industrial chaos?"

"The logic of the decision is exactly as you have stated," replied Mr. Edmonds, "but it is merely the logic of every other decision that has sustained a patent. The holder of a patent may impose any restriction and as many restrictions as he chooses to impose. In the Dick case, for example, if the license required that the mimeograph in question be used only on a table of solid gold, or that it be operated only by a blond woman whose molars were filled with gold, such requirements, however exaggerated and improbable they may appear, would be well within the rights of the patent holder. His monopoly guaranteed by the Constitution must be complete, else it is not monopoly. He can refuse to sell his patented article to anyone, and by the same token there is no law requiring anyone to purchase that article. Unless, for the purpose of acquiring a part of the patentee's statutory monopoly, the intending purchaser sees fit to comply with the patentee's terms, he may forego the use of the patented article or shop elsewhere. In point of fact, these things are perfectly self-regulating, and it is that regulation itself by which the interests of the public are protected. A patentee who imposes onerous or impossible conditions or unreasonable prices takes the most effective measure for throttling the market for his invention. In exactly the proportion that a patentee loads his licensee with onerous burdens, in that proportion does he risk finding no licensee to load with anything. This self-regulating feature of the license plan was well expressed by Judge Townsend in his decision in the case of Cortelyou vs. Johnson, 145 Fed. Rep., 937, decided in 1906."

Turning to the report of the case, Mr. Edmonds continued: "Judge Townsend held that the 'argument ab inconvenienti' (i. e., that the public might be inconvenienced or imposed upon by means of license restrictions), based upon the dangerous doctrine that public policy may nullify existing laws because said laws may be perverted by future unwarranted applications thereof, seems to be fallacious in theory and unwarranted in fact. . . . The self-interest of the patentee, seeking to derive a profit from his patent, will sufficiently protect the public against burdensome or unreasonable restrictions upon its use.

"Take, for example, the case of a motor car licensed under letters patent for use only with gasolene sold in Washington, the car would be purchased by no one who expected to run it farther than the Washington supply would permit. The major part of the business, possibly all of it, would go inevitably to the dealer willing to sell outright or whose license involved less onerous restrictions. If the vendor of the motor car first referred to were daring enough even to attempt a restriction so absurd as that suggested he would speedily be brought to his senses by decreasing sales, or no sales at all, with the result that he would be forced to adopt the plan either of unconditional sales or of sales upon conditions acceptable to users.

"In the case of the Dick mimeograph," went on Mr. Edmonds, "there is little or no profit derived from the manufacture and sale of the mimeograph itself. The cost of production is high, and, as in the case of many inventions, so is the selling cost. Of course, the Dick company might have set a high selling price on the instrument —say $50—but to have done so would have greatly contracted the market. Instead the price was set at about $30, which caused very many more of them to be sold and permitted very many persons to enjoy the benefits of the invention, who at the higher price would be debarred therefrom. In order to obtain a reasonable profit the mimeograph was sold subject to a license requiring that the supplies, such as ink and stencil paper used thereon, be purchased from the Dick company, a condition which is neither unreasonable nor unusual, and which is fair alike to the patentee and the public. In other words, the profit was derived from the sale of supplies and not from the mimeograph.

Digitized by Google

Mimeographs, like most other inventions, do not monopolize air, water or other elements of existence, and such restrictions, therefore, are not opposed to public policy. They are not articles of general use, but appeal only to a limited class. The Dick inventions opened up to the public commercial advantages and possibilities which theretofore the public utterly lacked. In those inventions the Dick company was granted a constitutional and statutory monopoly for a limited period. In that monopoly, and until its expiration, the public has no share save to the extent that the patentee, in the exercise of an undoubted right to exclude, lets the public in. No one, however, is forced to buy the mimeograph; whoever buys one does so of his own free will. To obtain a part of the patent monopoly, particularly on the attractive terms on which the machine is offered, he takes the machine subject to the conditions laid down by the patentee. In other words, he is free to take it or leave it, as he pleases. Our own law books are full of decisions sustaining the legality of this business plan. So are those of England. You will find that the British courts, including the Privy Council (corresponding to our Supreme Court), in dealing with cases analogous to the Dick litigation, have uniformly sustained the legality of the plan or practice in question, saying, in one case, that the contention of the patentee 'seems to be common sense and not to depend upon any patent law or any other particular law.'

"Chief Justice White, in his dissenting opinion is fearful that the monopoly enjoyed by patentees may be extended to dangerous limits; he fears that as the majority decision in the Dick case upholds the patentee's right to require that the ink used with his mimeograph be purchased from a certain source, and as the ink is unpatented, the patent law may be rendered so elastic as to embrace within the constitutional monopoly the control of unpatented articles, or of articles on which patents have been refused, or on which they may have expired.

"Personally," continued Mr. Edmonds. "I do not consider the point well taken. Such things, as I have already shown, are self-regulating. In the case of the mimeograph, while this may lawfully be used only with the patentee's supplies, there are no restrictions against the sale or use of ink broadly. Any ink maker is at liberty to sell his ink for any lawful use to which it can be put. In the particular case at bar, possibly the defendant's ink could be used to paint a reproduction of Whistler's 'London Street at Night.' They are free to sell it for that use. They are not, however, free to sell it for the express purpose of violating a patent or in aiding in the commission of any other tort. As with those defendants, so with the public at large. No one save the Dick company ever had the right to sell ink for use on the patented mimeograph. It follows, therefore, that no one is deprived of a right which was previously his by exclusion from the patentee's domain except to such extent as the patentee chooses to let him in. There is one other point that should not be overlooked. There are many inventions that are absolutely safeguarded by license conditions requiring that supplies be purchased from a particular source. In the case of the mimeograph, the ink used has a direct bearing on the quality of the work and the amount of the work which it can be made to produce. In one instance, an ink containing so much benzine was employed that it destroyed the stencil paper before 15 sheets of copy were run off, which is less than one-third or one-fourth of its normal capacity; this means that such ink not only tended to injure the reputation of the mimeograph but actually greatly increased the cost of operation to its purchasers. These facts are so elementary that I am surprised that the effort to distort them attained such strength."

"Is it not a fact," asked the Motor World man, "that in the so-called Bathtub Trust case the manufacturers concerned sought, under a patent covering a dredger for applying enamel to bathtubs to control the manufacture, sale and price of such tubs?"

"The facts, generally speaking, are as you state," responded Mr. Edmonds, "but the bathtub case and the Dick mimeograph case are in no way analogous except to the extent that the bathtub may be compared with the mimeograph ink. Neither the tubs nor the ink are patented, but we are not seeking to control the sale of the ink and impose no restrictions on its use. Also, as I understand it, in the bathtub suit it is not the patent but a contract or agreement or understanding between a number of manufacturers that is the real issue. It is this agreement or understanding which is claimed to be in restraint of trade. Without tearing down the Constitution, no such charge can lie against a patentee. What the court decided in the bathtub case is that, under the Sherman law, trade in an unpatented article may not be restrained merely because a patented machine or process was used in the manufacture of that article. The case did not, in the court's view, come under the patent law at all. In the Dick case, on the other hand, the patents covered the very thing—the mimeograph—the use of which was restricted.

"Nor is the so-called bicycle coaster brake litigation comparable with the Dick suit, as several papers have intimated is the case. As I understand it, the coaster brake situation grew out of a pooling of patents, which implies an agreement of some sort on the part of a number of manufacturers. The citing of this case and the bathtub suit, in both of which the charge is restraint of trade in violation of the Sherman law, is unfortunate; it simply has served to confuse the public mind and to distort the effect of the decision in the Dick case. The latter involved no pooling of patents, no agreements, no contracts, and the decision of the Supreme Court simply reaffirms the right of the patentee to enjoy to the full, for a period of 17 years, the fruits of his ingenuity. It is not in restraint of trade or violation of the Sherman law, because there could be and can be no trade in such mimeographs if the patentee but says the word.

"Congress was wise," vouchsafed Mr. Edmonds, "in granting such monopoly to patentees. I believe that making the possible reward so great has stimulated ingenuity and given the world many priceless benefits which otherwise it would not have enjoyed; I believe it has had as much as anything to do with the fact that, except for a comparatively few scientific discoveries, the United States is the country in which practically all of the most useful inventions have been born. Without such incentives as the law guarantees, I doubt that we would have had such inventions as Edison and Westinghouse, for instance, have given to us. And though, since the decision in the Dick case was rendered, a cry has gone up that our patent laws are 'rotten,' and that they should be revised by Congress, it will be a sorry day if the reward held out for invention is decreased or restricted.

"In the cry that has gone up concerning the 'rottenness' of our patent system," went on Mr. Edmonds, "the laws of other countries have been cited and certain writers have made much of the laws in Germany, for instance, which, until the recent treaty, required that unless a patent be 'worked'—that is, unless the article at stake be actually manufactured in Germany within a period of three years—the invention will become public property. As a matter of fact, however, patent lawyers are well aware that this requirement, even in Germany, does not mean all that it says. When the three-year period is about to expire it is simply necessary for a patentee to advertise his article for sale, and if he is able to prove to the court that the advertisements brought no responses, and that therefore there was no demand for his invention at that time, the 'working law' does not abridge the life of the patent."

"But," queried the interviewer, as he prepared to take his leave, "are not our patent laws 'rotten' to this extent: That when an inventor receives a patent he obtains little more than a license to sue? Is it not a fact that although his patent may bear the seal of the United States it is of practically no value until it is litigated, and that such a state of affairs operates against the inventor of modest means?"

"You have hit the nail squarely on the head," replied Mr. Edmonds. "That is the most regrettable feature of our patent system. The grant of a patent on a really meritorious invention often is a signal to imitators, and the result is litigation, protracted, expensive and harrassing, which often makes the useful life of a patent nearer seven years than 17."

SETTLEMENT OF TAXICAB STRIKE

Conditions as Meted Out by British Court of Arbitration—Drivers Get the Best of Their Employers.

Following temporary mediation permitting drivers to continue to work, with the understanding that their compensation during the period of cessation of hostilities finally would be adjusted according to the award of the court of arbitration appointed by the London Board of Trade, the dispute between the taxicab drivers and their employers, which precipitated the recent strike at last has been amicably settled.

That the settlement is perfectly satisfactory to the drivers is beyond dispute, for not only are they permitted to take possession of the "extras"—over which the dispute originally arose—but, in addition, certain other matters, including the fixing of the cost of "petrol" as supplied by the companies to their drivers, have been decided in such a manner that hereafter there scarce can be anything but joy in the heart of the London taxicab driver. But if the settlement is satisfactory to the drivers, who actually obtain a great deal more than they asked for or expected, it is equally unsatisfactory to the employers. So unsatisfactory is it, in fact, that dirges have gone up and the immediate demise of all small companies and the not far removed failure of even the larger ones freely is predicted. That is, if the fares—and particularly the initial fare, which, for horsed vehicles, now is one shilling (25 cents), as against 8 pence (16 cents) for motor vehicles—are not raised. That they eventually will be raised appears within reason, for, though they are fixed by law and cannot be changed without proper authority, there is little doubt but that the companies will be able to produce figures of such a nature as to ensure the passage of the desired legislation. The principal awards are as follows:

"1. The extras belong to the drivers.

"2. The drivers' proportion of takings to be 25 per cent.

"3. No rank or station charges to be allowed by the employers.

"4. The employers to supply the drivers with petrol at a fixed price of 16 cents a gallon for the current year, and either to allow mileage at the rate of a gallon for 18 miles, or to give half a gallon per day free. In future years the price of petrol to be fixed by the Conciliation Board, so that the charge to the drivers bears about the same relation as now to the price the employers themselves pay.

"5. The drivers to take cabs out six days per week, or 66 hours per week; no day to exceed 15 hours. Cabs are to be kept for the regular drivers till a reasonable hour (the precise time under varying conditions being specified in the award). Odd men waiting in the garage are to be allowed 12 cents for each full hour's waiting time at which they are requested to come, with a minimum allowance of 25 cents; half rates for waiting time to be allowed to odd men to whom cabs are allotted.

"6. The driver not to be required to pay in at once the sum which he alleges he has lost by a 'bilk' if he can give the name and address of a policeman or other trustworthy person whose evidence he could produce in proof of his allegation when the matter is investigated.

"7. The system of issuing 'stop notes' gives no reasonable ground for complaint, and the charge of boycotting has not been proved. The rules of the employers' association to be modified so as to make it clear that reports on drivers circulated among its members should be confined to matters of serious importance.

"8. Agreements between employers and drivers, if legally practicable, to be so framed as to bring the drivers within the Workingmen's Compensation Act."

That the traffic regulations at present in force are not suitable to the modern system of transportation by taxicab is the opinion of the court, rendered in a supplement to the award, in which it is advocated that "if the principle of a special license and fare for distant suburbs could be embodied in a practical scheme, advantage might result to the public, the employers and the drivers by the diffusion over a wider area of the present excessive supply of cabs in the more central districts." And further it is noted: "It appears from the evidence that the average takings of a cab are much decreasing, and this is attributed by the drivers to the supply of cabs being in excess of the demand." After consideration as to whether any limitation could be imposed by the licensing authority on the number of cabs licensed, such procedure was deemed inadvisable "in the interest of the public." "While such a limitation would be accepted by the employers," the court said, in conclusion, "the drivers are opposed to it, while the employers object to a limitation of the number of drivers."

Detroit Selected for S. A. E. Meeting.

Detroit finally has been selected as the place for the annual mid-summer meeting of the Society of Automobile Engineers, which has been fixed to occur June 27, 28 and 29. Although there was considerable sentiment in favor of Atlantic City, Asbury Park or some other Eastern seashore resort, Detroit's supremacy, from the industrial standpoint, won the day.

Acetylene That Causes More Heat.

When kerosene lamps are converted to use acetylene, care should be taken to set the new burners as low as possible, the reason being that acetylene creates more heat, which may cause injury.

WHY NEW YORK'S TIRE-DATING BILL

Sheriff Had Trouble and His Legislative Friends Proved Obliging—But Measure Not Likely to Pass.

As the Legislature adjourns to-morrow, and although the bill pending in the New York Legislature which seeks to require the dating of tires under penalty of $50 for each violation has reached the order of final passage, it is not likely to become a law. Senator Roosevelt, who is one of the sponsors of the bill, admitted as much when seen in Albany by a Motor World representative on Tuesday last. The bill was slightly amended on the 20th inst., the amendment in no way affecting its objectionable nature, however, but serving to delay final action.

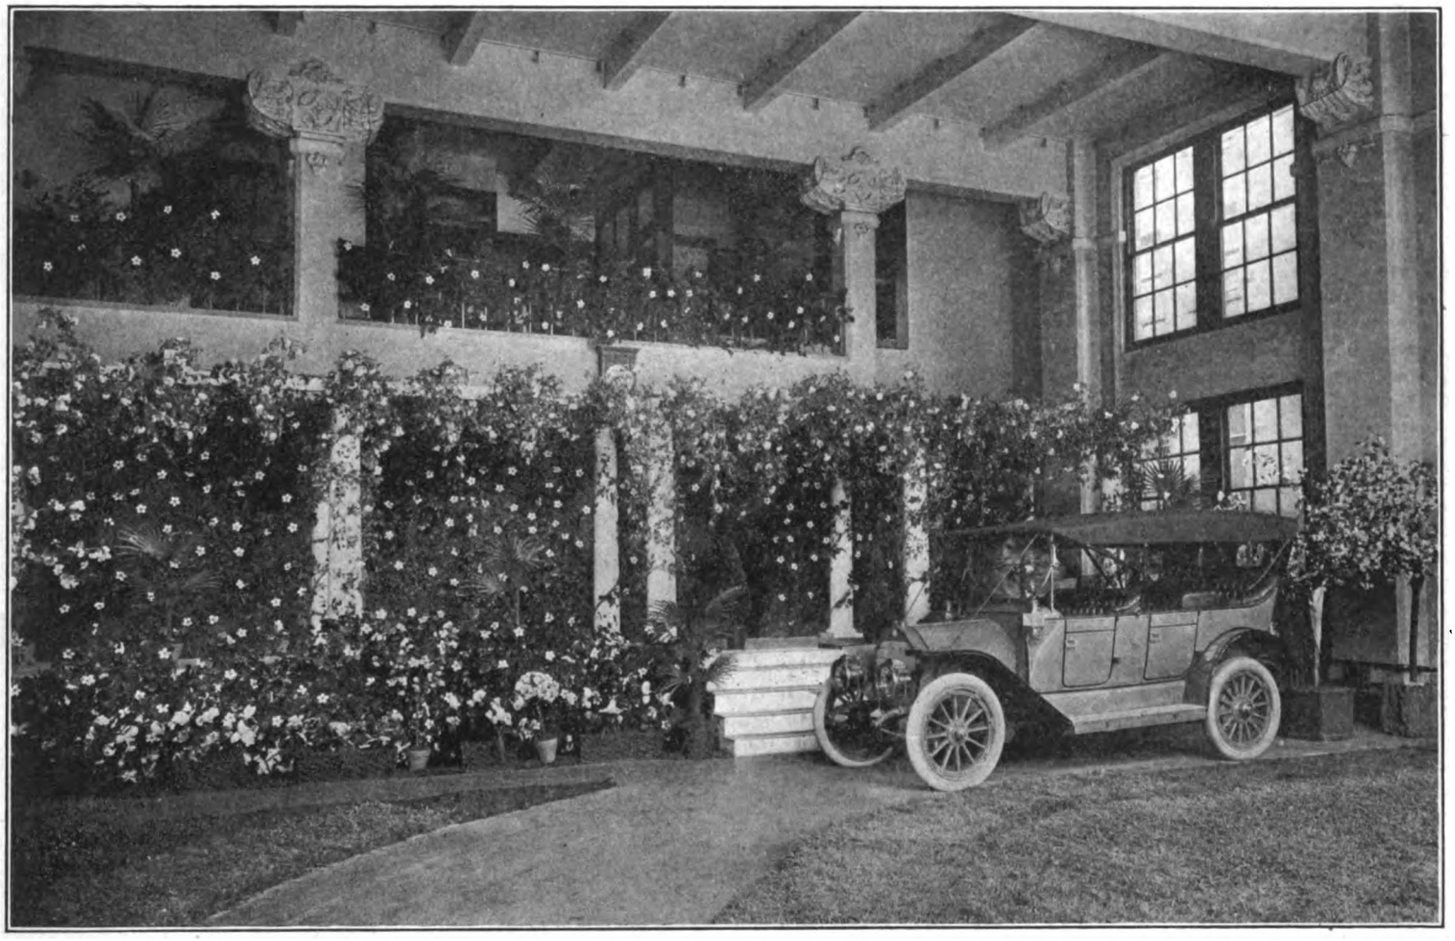
The introduction of the bill in the New York Legislature was one of the unexpected developments of the legislative session. A similar measure was enacted in Minnesota last year, and one was threatened in Georgia, which facts suggest that the New York bill was inspired by interests unfriendly to the automobile tire manufacturers. If it had been fathered by other than Senator Roosevelt and Assemblyman Chanler, both of whom hail from Dutchess County, it might have been viewed as a "strike" bill, but as these two lawmakers do not rank as "strikers" the wonder grew that they should lend themselves to the support of such an act.

In an endeavor to discover just what was behind the bill, the Motor World man asked Senator Roosevelt point blank who or what had inspired it. His reply brought out how far even the displeasure of a sheriff may reach.

"The bill was suggested by the sheriff of Dutchess County," said the senator. "He had some trouble with the tires on his automobile and stated that he believed it would be a wise thing to have manufacturers put a date on their tires, so that purchasers could see with their own eyes whether they were getting tires that had deteriorated, and were, therefore, more liable than newly made tires to blow up. I accordingly introduced the bill, to which," the senator mildly stated, "I understand there has been considerable objection.

"I am not sure, however, that the bill will go through this year," he added.

Senator Roosevelt has become possessed of the notion that because the bill as amended gives the manufacturers until January 1, 1914, instead of January 1, 1913, as originally proposed, to conform to its requirements, it will not now meet with serious objection.



Assemblyman Chanler, who at one time was lieutenant-governor of the State, was not in Albany, but as he, also, hails from Duchess county, his source of inspiration is fairly clear.

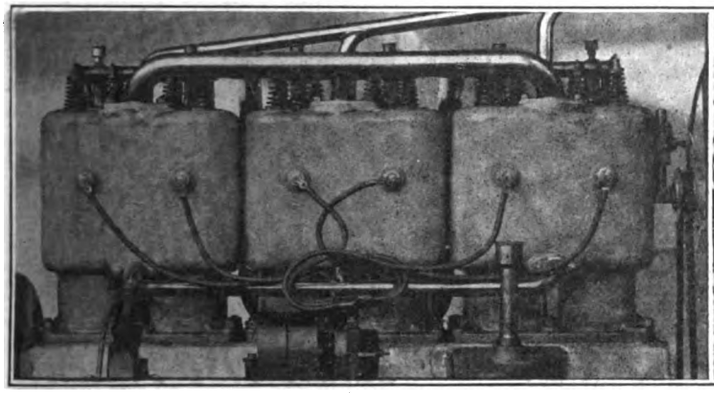
STORE STRIKINGLY TRANSFORMED

Philadelphia Branch Sets a New Mark in Embellishment—Unusual and Enticing "Properties" Charmingly Arranged.

It is not often the interior of a salesroom can be so transformed as to bear a strong resemblance to a suburban scene, with all the correct "properties" of front porch, grass, flowers and so on; but this is exactly what has been done by the United Motor Philadelphia Co. in prosecuting what is styled a "campaign against needlessly high prices for motor cars;" it constitutes a feature of "Saybrook Week." The interior of the salesroom on Broad street has been very cleverly arranged with real blooming flowers, potted plants and other decorative accessories so that, as the accompanying illustration shows, it looks about as little like an automobile salesroom as it is possible for such a place to look. It might be the front of a suburban residence, with a touring car—incidentally, the car is a Stoddard-Dayton Saybrook, and the whole show was arranged as a setting for it—waiting for the family to come out and go for a spin. The piazza steps and the bit of roadway in the foreground add an irresistible touch of realism that is helped out by the grassy bank. Or it might be, as the "landscape gardeners" suggest, a "corner of a shady country estate, showing a real Italian pergola on the knoll of a lawn." Whatever impression the scene makes on the individual beholder, however, the fact remains that the idea is a very clever one and the effect is as attractive as it is unusual and well executed.

STODDARD-DAYTON'S PHILADELPHIA SHOWROOM WITH ITS STRIKING SETTING

"Electrobuses" for Vienna Streets.



Though the electric vehicle in the concrete is passing through an exceptionally protracted period of adolescense on foreign shores, there is no lack of indications that its development at length has reached to the stage where its genuine merit in certain fields gradually is being realized. The latest indication is the adoption of electric 'buses—"electrobuses," they are styled—of the most improved type for use in the city of Vienna. In adopting "single deckers," the experience of the French Compagnie Generale des Omnibus is reflected, this type of vehicle having been found, after exhaustive tests, to be the most efficient, both as regards passenger-carrying capacity and maintenance. For propulsive power batteries alone are relied upon, these being carried in two trays below the chassis frame. Each tray, which is readily demountable for inspection and charging of the batteries, contains 42 Tudor cells, the total capacity being 244 ampere-hours. The motors are enclosed in the front wheels and are of of the Lohner-Porsche type, as supplied by the Austrian-Daimler Co., which company holds the manufacturing rights for the system. The motors are wound for voltages varying from 160 to 220, and under normal conditions are rated at 15 horsepower each. The wheels are shod with single rubber tires 31 inches in diameter, and weigh approximately 700 pounds each. The battery alone weighs 1,500 pounds, and the combined weight of the chassis and body is 3,950 pounds; with a full quota of passengers the total weight of the 'bus is 9,360 pounds. In springing the vehicle special precautions to eliminate as much as possible the effect of road vibration on the batteries and the passengers have been taken, and to this end the chassis is mounted fore and aft on semi-elliptic springs supplemented by Lemoine pneumatic cushions. For entrance and exit, a single side door is provided and this gives access to two compartments, the rear compartment, where smoking is prohibited, being arranged to seat 10 passengers. The front compartment, where smoking is allowed, accommodates eight more passengers, four seated and four standing.

SPARK PLUG LOCATION AND ITS RELATION TO POWER

The Necessity for Flame Propagation of Maximum Rapidity and the Influence of Proper Plug Positioning on Combustion—Loss of Heat and Consequent Lowering of Thermal Efficiency That Is Caused by Poor Locations—Varying Practices in Vogue.

It is probable that there are few who fully realize exactly what ultimate effect the position of the spark plugs may have on the power output of a given engine. Having become accustomed to the location of plugs in one of several positions, and as the manufacture of the plugs themselves has reached such a state of perfection that they seldom require attention, it is perhaps natural that their location in the engine should be taken as a matter of course. But that their position has a definite bearing on power output—to say nothing of smoothness of operation—is a comparatively simple matter to establish and its establishment cannot fail to be of interest.

McFARLAN SPARK PLUG LOCATION

ILLUSTRATIVE OF PALMER & SINGER DESIGN

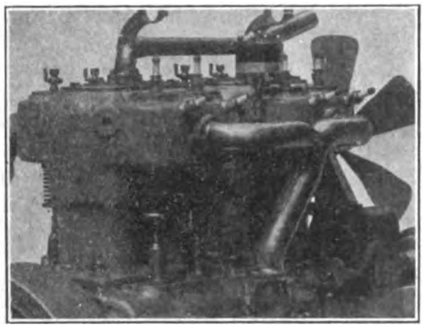
Because the internal combustion engine is essentially a heat engine it is necessary, in order to obtain the power—and, incidentally, the greatest efficiency—to obtain the maximum permissible degree of heat within the cylinders consistent with the operation of the engine as controlled by the movement of the pistons. If the temperature is too high, either excessive expansion or lack of lubrication, or both, may cause the pistons to stick, and if the temperature is too low power is lost, for the mechanical equivalent of heat is directly proportional to the horsepower.

The British unit of heat, or British thermal unit (B. T. U.), which is the standard as generally recognized, except in France, where the French equivalent, or "calorie," is used, represents the quantity of heat which is required to raise the temperature of one pound of pure water one degree Fahrenheit at or near 39.1 degrees Fahrenheit, which is the temperature at which water is at its maximum density.

The mechanical equivalent of heat is the number of foot-pounds of mechanical energy which is equal to one British thermal unit, heat and mechanical energy being mutually convertible. According to early experiments, those of Joule being made in 1843-50, the mechanical equivalent of one B. T. U. was determined to be 772, which figure is known as Joule's equivalent. Later experiments, however, notably those of Professor Rowland, made in 1880, give higher values, and the most probable average now is considered to be 778.

From which is may be gathered that as one horsepower is equivalent to 33,000 foot-pounds a minute, it also is equivalent to $\frac{33{,}000}{778}$, or 42.416 British thermal units a minute. If it be assumed that a given engine is 100 per cent. thermally efficient, which is impossible, and is capable of delivering exactly one horsepower, then there must be generated in its combustion space 42.416 heat units per minute, or 2,545 heat units per horsepower-hour. If, however, less than 42.416 heat units per minute are generated, then the horsepower will be decreased in direct proportion to the decreased number of heat units generated. For instance: If, due to faulty carburation or ignition, only 40 heat units per minute are generated, then available horsepower (assuming 100 per cent. thermal efficiency) will be represented by the equation $\frac{40 \times 778}{42.416} = 0.733$ horsepower.

Naturally, a great deal depends on carburation. If the gas is too rich, or too poor, it will not burn porperly, and the maximum number of heat units will not be generated. It has been established that the proportions of gasolene and air in the mixture must be determined within comparatively close limits in order to obtain a theoretically perfect mixture. Thanks to the ingenuity of engineers, however, carburetters are about as perfect as they are likely ever to be, and it is not difficult—with considerable patience necessary, in some cases—to obtain proper adjustment.

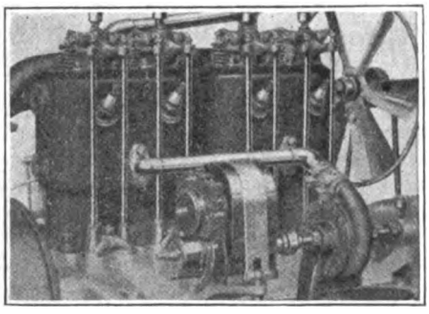


Therefore let it be assumed that carburation is perfect and it may be appreciated that the power output depends to an even greater extent on proper ignition of the charges in the cylinders. Given properly located plugs—the location having been chosen with due regard to the feasibility of obtaining the maximum power under ideal conditions of carburetter adjustment—and an efficient source of ignition current, such, for instance, as a reputable high tension magneto, and even a radically wrong carburetter adjustment will give results of a kind. With badly located plugs, or a weak spark, however, often even the best mixture obtainable cannot be reconciled to the wofully "flat" power output curve, ordinates and abscissas representing the revolutions per minute and the horsepower, respectively.

As a stone thrown into the center of a pond will cause a succession of ripples extending in a circle of ever increasing diameter until the banks are reached, so is the flame propagation in the cylinders of an internal combustion engine. For instance, if the stone be thrown into the exact center of the pond, the distance the ripples will spread in a given time unit will be double the distance they would spread if the stone were thrown near one of the edges. In one case the ripples extend in all directions

Digitized by Google

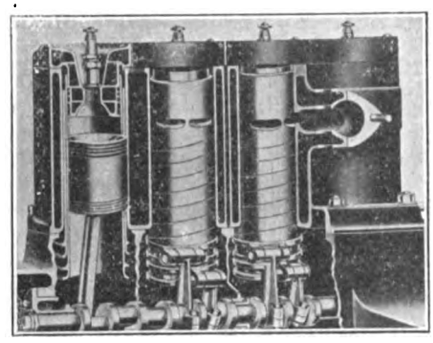
with equal velocity and in the other case the ripples can extend only in one general direction; hence they reach to but half the distance in the same length of time. The propagation of the flame follows the same general principle, and, as is fairly well known, it is not instantaneous.



That there is an appreciable length of time between the occurrence of the spark and the combustion of the complete charge in a cylinder has been demonstrated time and again, and it is because of this lag that the location of spark plugs bears such a di-

DISPOSITION OF CORBIN PLUGS

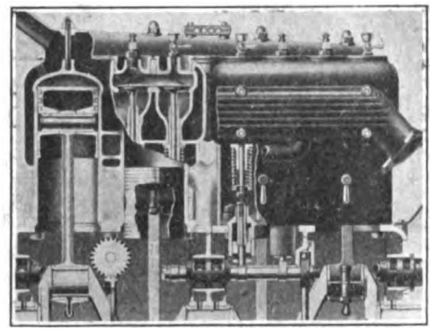
rect influence on power output and thermal efficiency.



When the mixture is compressed in one of the cylinders of an internal combustion engine a certain amount of power is absorbed in compressing it. It is reasonable to expect, therefore, that part, at least, of that power may be reclaimed, and it is as represented by the proneness of the gas to spread out and again occupy the space

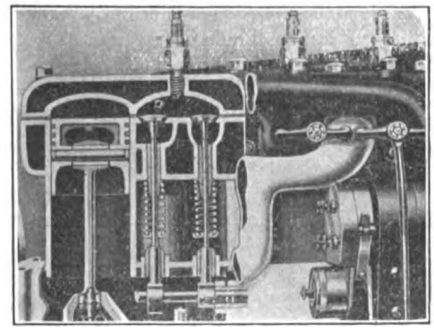
ILLUSTRATING BUICK DESIGN

it occupied before compression; the volume of gas involved, however, remains the same whether it is compressed or uncompressed. But when the gas is ignited its volume is immediately increased and its composition is changed. The combustion of the gas causes the generation of a certain number of heat units, the number varying according to the completeness of combustion and the cubic capacity of the combustion space.



If all the heat units could be converted directly into power then the engine would be 100 per cent. thermally efficient; but they cannot be so converted. When internal combustion engines first became a commercial possibility 16 per cent thermal efficiency was considered to be high; at present, however, from 30 to 40 per cent. thermal efficiency is the average, though as high as 51 per cent. has been obtained in laboratory work. Part of the heat is dissipated into the air and part is absorbed

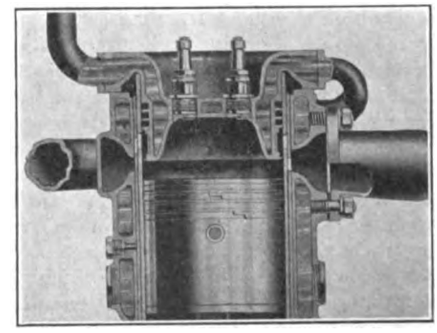
STEARNS-KNIGHT CENTERED PLUGS



by the cooling water, or the cooling air, as the case may be.

If, however, to obtain, say, 40 horsepower, the engineer allows for the generation of a sufficient number of heat units

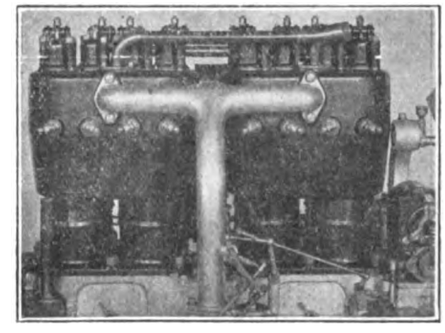
MARION PLUGS OVER INTAKES



to allow of a loss of, say, 65 per cent., and more than 65 per cent. is lost, through one cause or another, less than 40 horsepower is obtained from the engine. If the carburation is correct, it is up to the

METZ SPARK PLUG ARRANGEMENT

ignition, in that the flame propagation is not rapid enough. At high engine speeds it is quite possible that piston speeds may be high enough to cause burning or unburnt gases to be ejected. In which case it is quite plain that a certain number of heat units which might be utilized are lost and not converted into energy. In other words, assuming the ignition spark to be 100 per cent. efficient, the improper location of spark plugs may be directly responsible for power loss because the flame propagation cannot be as rapid as it might be under better circumstances.



To return to the stone in the pond example, it appears, therefore, that the best possible location for the spark plugs is directly in the center of the combustion space in order that flame propagation may be most rapid. Actual tests have

COLUMBIA-KNIGHT TWIN PLUGS

demonstrated that the more rapid is flame propagation the greater is the power output, within certain limits. For example might be cited the experiments with two-point ignition, the results being an increase in power of as much as 20 per cent. under propitious conditions.

Of course, such lag as there is between the occurrence of the spark and the complete combustion of the mixture always is

POPE-HARTFORD PRACTICE

allowed for, though the method of allowance is in itself a compromise. The spark is timed to take place sufficiently in advance, according to piston speed, to allow of complete combustion by the time the piston has passed top dead center and started its power stroke. From which it may be appreciated that part, at least, of the mixture must be fired before the piston reaches top dead center, in which case part of the inertia of the fly-wheel is absorbed in overcoming the power of that part of the mixture which has been burned.

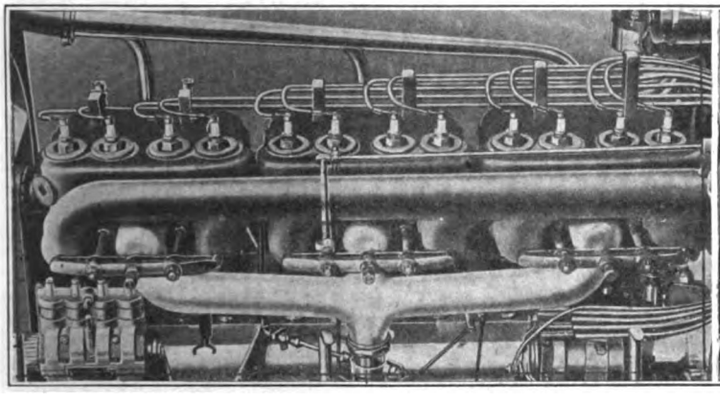
Consequently, the more rapid the flame propagation is the less in advance will the spark be required to be timed, and a greater proportion of energy will be con-

Digitized by Google

verted to useful purposes. Hence, it is desirable that flame propagation be as rapid as possible if the maximum power is to be obtained, and, as has already been pointed out, the position of the plugs bears a definite relation to flame propagation.

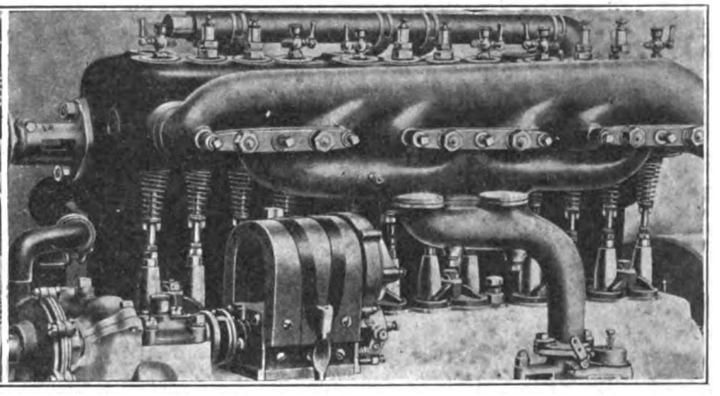
The central ignition of charges is not a new idea; it has been advocated before, though up to to the present time very few manufacturers have so constructed their engines that plugs may be centrally located. Practically the only exponents of the system at present are to be found in the ranks of the manufacturers of Knight engines. In the Stearns-Knight, for instance, a single plug is located directly in the center of the combustion space, as shown in the accompanying illustration. In Columbia-Knight engines, however, a slightly larger space is available, and two plugs are inserted in each cylinder head. Either of them is sufficiently near to the center of the combustion space to be considered in the center for all practical purposes. It seems within reason that part, at least, of the extra power per cubic inch of gas fired that is shown by Knight engines may be traced directly to the central location of the spark plugs.

Because the T-head or L-head type of cylinders are the most popular, as involving, possibly, the least mechanical complication in construction of the valve parts, and as the water outlet almost invariably is placed on top of the cylinders, spark plugs have come to be located over the valve pockets, in many cases in the valve pockets, quite as a matter of course. But there is another reason for such locations, and in particular for the location of the plugs over the intake valves. The plugs operate under very adverse conditions; half the time they are subjected to the intense heat of the burning gases, and unless they are cooled as much as possible are likely to become so hot as to cause pre-ignition. When they are placed over the intake valves, however, the cool in-rushing gas reduces their temperature.



Typical examples of such plug locations may be found in a very great many cars, two which exemplify the general construction being shown herewith. In the Mitchell engine there are but six plugs for the six cylinders, and close examination of the picture will reveal that in each case the plugs are located over the intake valves. Incidentally, this location insures that the sparking points will be in contact with "live" gas after the induction stroke. In the Winton engine, which is shown beside the Mitchell and is also of the six-cylinder variety, twelve plugs are used. Each set of six is used independently, the set over the intake valves serving for ignition by means of the magneto, as under normal running conditions, and the other set operating through the medium of a battery.

When inserting new plugs in an engine great care should be taken to see that the points do not protrude too far and that they do not approximate the other extreme in their location at the end of a deep recess in the valve caps. In the first case there is danger of pre-ignition, for the reason that the protruding shell of the plug is not in contact with the cooled metal of the cylinder head. In the second place, ignition may be faulty, because it is practically impossible for "live" gas to reach to the spark points. For the best possible results the plug points should protrude just beyond the valve cap or the cylinder wall, as the case may be. The Marion engine, illustrated herewith, partly sectioned, shows a representative plug location, the plugs being over the intake valves and exactly "fitting" the valve caps. In the Metz arrangement, the location of the plugs is equally good. As there are no valve caps, the whole cylinder head being removable, the plugs have been arbitrarily placed over both valves and between them. Corbin construction is an interesting example of the faith of the manufacturer in the efficacy of locating the plugs over the intake valves. In this case the service plugs are located in the orthodox position in the valve caps and the reserve, or battery set, is located at an angle projecting into the intake valve pockets.



Naturally, when valves are of the overhead type, and, with the water outlet connections, occupy all the available space on top of the cylinders, it is necessary to find some other location for the plugs, and the general practice is to tap through the water jacket and cylinder wall so as to admit the plugs horizontally into the combustion space from the sides. Such construction is embodied in the McFarlan engine, illustrated herewith, and in several others. This method of cylinder construction is not entirely confined to manufacturers of "valve-in-the-head" motors, however. As a representative of the T-head type motor, with the plugs set horizontally into the valve pockets, the Palmer & Singer motor is not quite, though almost, alone.

In the Pope-Hartford motor the method of arranging the plugs is quite similar to that used in the McFarlan, except that they are placed at a slight angle to the axis of the pistons, the reason being to obtain somewhat greater accessibility and to facilitate their removal. Slightly different, the location of the plugs in the Buick engines still follows the same general plan, though there is a clever theory involved in the unusual angle at which they are set. Heretofore they have been set horizontally, but after considerable experimenting it was determined that setting them at an angle reduced to the minimum the probability of lubricating oil or soot remaining on the spark points for any length of time.

It is obvious, of course, that spark plugs should be so located as to be readily accessible, for despite the fact that they are practically infallible in their present perfected forms, it is essential that they be easily and quickly removable, without the necessity for recourse to special tools which may or may not be in the tool kit when it is urgent that a plug be changed. It is perfectly true that there may come a day when the necessity for the spark plug will be no more—the answer is to be found in the Diesel engine, which uses no other source of ignition than the heat of compression—but that day is long removed. In the meantime, the spark plug will continue to occupy its particular niche in the scheme of things pertaining to automobiles, and though it scarcely can be expected that further improvements in the plugs themselves will be made, it is not unlikely that the future will see greater attention paid to the location of plugs in the cylinders.

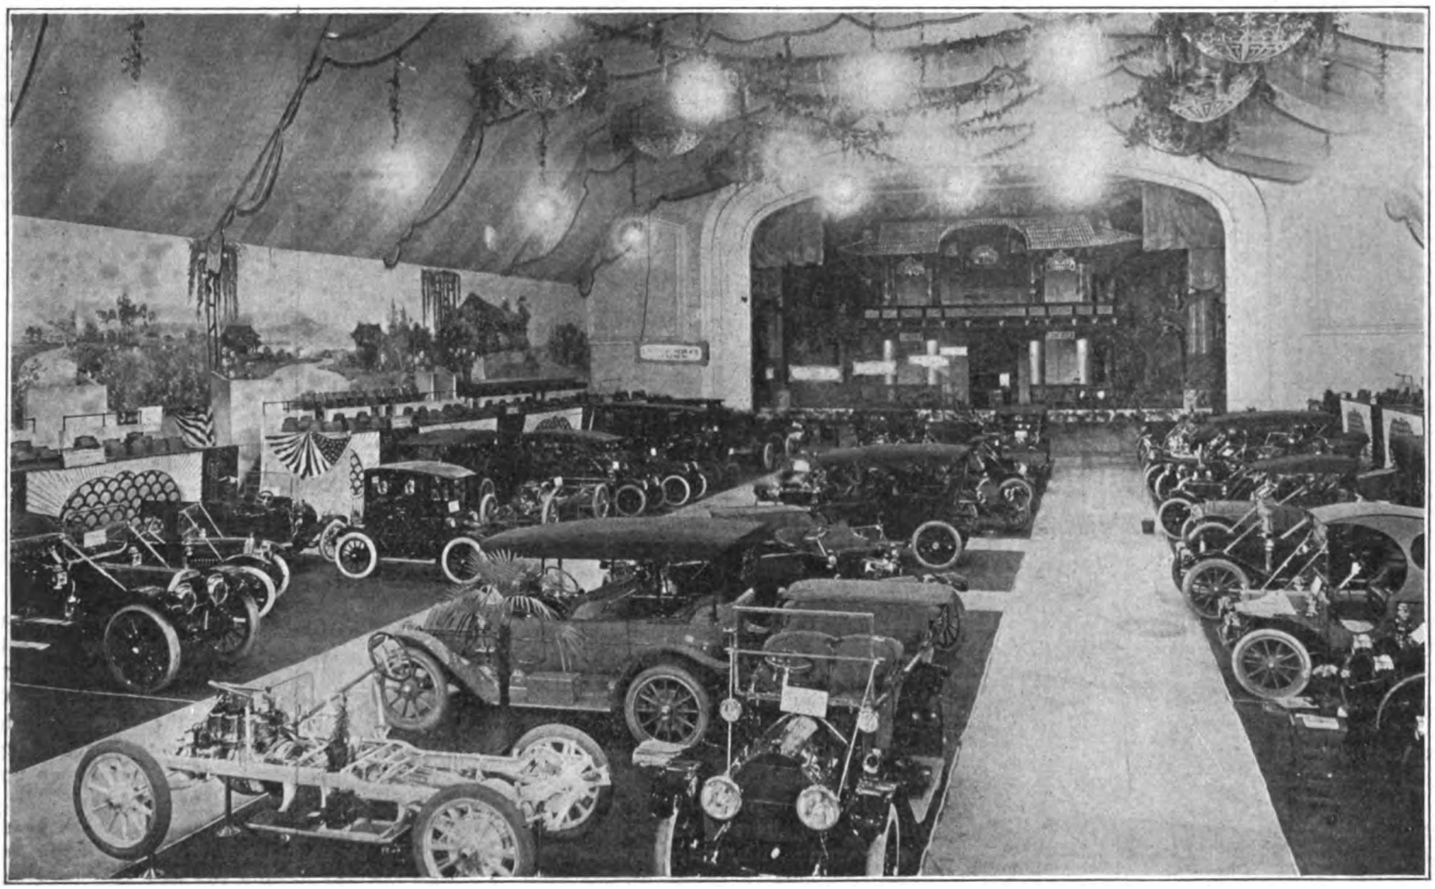
INCENSE BURNED AT KANSAS SHOW

Wichita's Exhibition Novel in More Than One Sense—Both the Eye and the Nose Were "Tickled."



If a pretty setting and a realistic setting were the only requisites of a successful automobile show, the Wichita (Kan.) Business Association certainly had smooth sailing with its first annual exhibit, which was launched in the Wichita Forum during the week March 18th to 23d. But the decorations, which really were beautiful, did not eclipse the display of motor cars, trucks and accessories. There were too many of them to be eclipsed—from one to three of each of the 27 different makes which were staged by 19 exhibitors of motor vehicles, while all varieties of supplies and accessories were on hand, shown by the dozen equipment dealers.

The more or less inclement weather which prevailed throughout the week had very little or no effect on the attendance; indeed, it seemed as if the gentle spring showers but enhanced the beauty of the Japanese garden setting, the brightness and freshness of which offered a decided contrast to the murky darkness reigning outside of the four walls of the building. The arena was well illuminated with the soft glow which issued from numerous chandeliers, which took the form of massive flower-laden baskets, and which extended in two rows through the length of the room. Garlands of smilax and wild moss, the streamers of delicately tinted Japanese bunting extended from each of the luminous flower baskets to the nearest chandeliers on one side and to the ceiling on the other side. The huge canvas panel which surrounded the whole arena save on the side occupied by the stage depicted various and interesting Oriental scenes.

Music, which was furnished by Bamberger's orchestra, issued intermittently from the truly Oriental structure which occupied the major portion of the stage, the joss house. The touch of realism which was felt by each of the visitors was not, however, gained in its entirety through the sense of sight. The mingled odors of the brewing Japanese national drink which prevailed in the vicinity of a small tea house which shared the stage with the other structure, and the burning incense issuing from the joss house, too, had their effect.

The exhibitors were as follows: International Harvester Co., International commercial; Arnold Automobile Co., Auburn; Studebaker Corporation, E-M-F and Flanders; George W. Lewis, Mitchell; Cadillac Service Station, Cadillac; J. I. Case Threshing Machine Co., Case; Wichita-Overland Co., Overland and Hudson; Velie Motor Sales Co., Velie; Peru-Van Zant Co., Marathon; J. M. Kirkwood, Oldsmobile, Paige-Detroit, Lexington and Hupp-Yeats electric; J. Arch Butts, Buick; Anderson Electric Car Co., Detroit electric; G. A. Jones, R-C-H and Wichita Falls truck; Wichita Automobile Co., Pierce-Arrow, Chalmers, Reo and Waverley electric; Gordon Oldham, Stearns; Mason Motor Car Co., Mason; Regal Motor Sales Co., Regal; Baker Motor Vehicle Co., Baker electric; Westcott Motor Co., Westcott.

The accessory exhibitors were: Vehicle Supply Co., Uncle Sam Oil Co., Hockaday Supply Co., National Oil Refining Co., Auto Tire Filler Co., Hays-Wayne Pump Line Co., G. A. Fralich Supply Co., Auto Top Co., J. Arch Butts, Wichita Auto Garage, Auto Supply Co., Walker Bros.

WICHITA'S HANDSOME SHOW INCLUDING THE JOSS HOUSE BUT MINUS THE INCENSE

Carbon That Causes Increased Power.

Carbon deposit in the combustion spaces of a motor may not always make its presence felt by reason of loss of power and knocks. On the contrary, the symptom may be an increase of power and accelerative properties, the reason being that the combustion space is slightly decreased in volume, causing higher compression and, within certain limits, greater power. As a general rule, such symptoms may be taken to mean that a small accumulation of carbon exists and care should be taken to remove it. If it is not removed it will increase rapidly and the symptoms will change to knocks and serious loss of power.

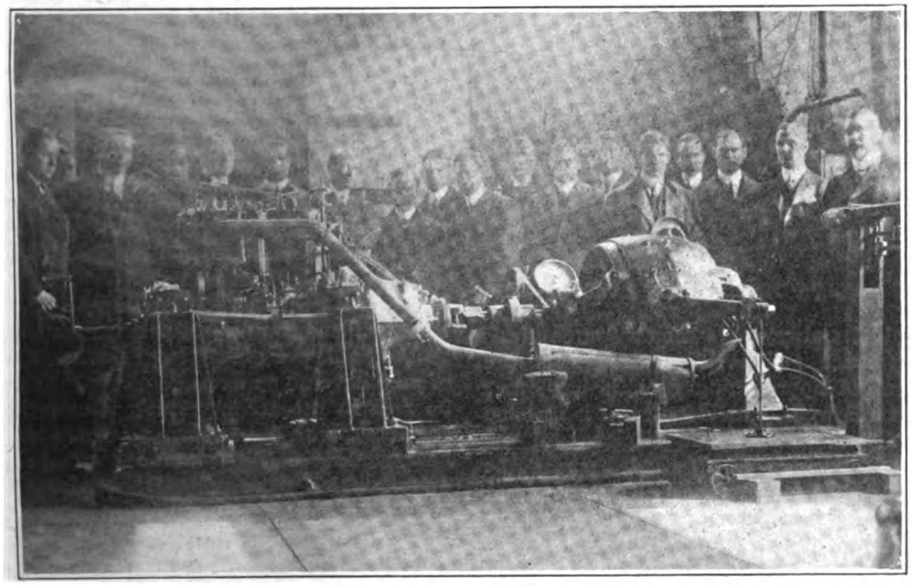
CUT-OUT'S WORTHLESSNESS PROVEN



Laboratory Test Emphasizes Belief That Its Chief Service is to Create Noise—The Testing Apparatus Employed.

Confirmation of the belief and knowledge that not only is the cut-out unnecessary with an efficient muffler, but it makes so little difference in the power available as to make its use unwarranted, was the chief result of tests made one day last week at the laboratory of Joseph Tracy, at Rutherford, N. J., under the auspices of the so-called Touring Club of America.

The tests were made with a Packard 30 horsepower motor of stock pattern, with the regular Packard muffler. The testing apparatus consisted of a dynamo, to which the motor was direct connected by means of a jointed shaft, having a field casting that was mounted in bearings which would permit it rotate if not checked. An arm attached to the field casting rested on the platform of a scale. When the motor was running the current generated was absorbed by a resistance, and the magnetic drag of the armature on the field caused the latter to exert a pressure through the projecting arm on the scale, the pressure being at all times in proportion to the power developed by the motor. Readings were taken at speeds varing from 300 revolutions per minute to 1,800 revolutions per minute, beginning at the lower figure and increasing by steps of 100 revolutions per minute. The figures first given out as the result of the test were of necessity somewhat hastily compiled, and a subsequent checking with the curves plotted gave slightly different results. In fact, the test was so hastily arranged as a publicity stunt for the so-called Touring Club that it was by no means satisfactory. As the appended table shows, however, there still remain some curious figures, which seem to indicate that there are some speeds at which the power output of the motor was actually greater with the muffler cut-out closed than with it open.

Muffler Cut-Out Test.

TESTING THE MUFFLER CUT-OUT IN THE TRACY LABORATORY

To Remove Dents from Copper Piping.

Where copper piping is used in the make-up of either the intake manifold or the water circulating system, a dent not only mars the appearance, but may perchance cause more or less trouble by reason of the reduced effective cross section of the pipe. If the pipe is a straight one the dent can be readily removed by inserting a cylinder of hard wood, the diameter of which is slightly less than the inside diameter of the pipe, and by gentle force tapping it past the dented portion. When "L" or other bends are present this method cannot be applied. The best way is to plug up one end of the pipe with a hard wood plug. Run the pipe full of an alloy made of 8 parts of lead, 15 parts of bismuth and 2 parts of mercury, and when it has ocoled so that the filler is in a plastic state gently tap the alloy. This will force out the dented portion, after which the metal can readily be removed by remelting.

BEAVER ADDS BLOCK-TYPE MOTOR

Wisconsin Makers Depart from Previous Practice—New Engine Has Long Stroke and Discloses Ingenuity.

Supplementing an already extensive line of motors and unit power plants, the Beaver Mfg. Co., of Milwaukee, Wis., has added still another model which bears all the ear-marks of Beaver quality but which it just a step in advance of other models in that it reflects the very latest engineering practice, which means the greatest possible simplicity consistent with the functions which must be performed; accessibility follows as a matter of course. The new motor is of the true long-stroke type, the four cylinders being cast in a single block and measuring 3½ inches bore and 5 inches stroke.

Carrying the system of block casting a little further than is usual, only one other American motor being so constructed, the top half of the crank case is cast integral with the cylinders, which eliminates the possibility of lubricating oil seeping through between the base of the cylinders and the crank case, and therefore conduces to cleanliness and economy of oil. Solidity of construction also is increased, of course. The crank shaft is of the two-bearing type, the main bearings as well as those of the connecting rods being of exceptional size. The crank shaft itself is forged from a solid billet of carbon steel, and is two inches in diameter. Reflecting the simplicity which has been aimed at and achieved, the water circulation pump has been eliminated, cooling being effected by the thermo-siphon system, the theory being that this system is more efficient by reason of the fact that the water does not commence to circulate until the motor has become warmed up. Thereafter the water is maintained in circulation, and consequently cooled, according to the heat of the engine. Lubrication is effected by means of the constant level splash system operating on the vacuum principle, the oil reservoirs being cast integral with the lower half of the crank case; they are of ample capacity for 300 miles' running, under normal conditions.

Particular pains have been taken to ensure quietness of action, and to this end the valves and their method of actuation have been given a greater amount of attention than is usual. In the first place, the cooling water circulates completely around the valve heads and stems, which is in itself a practical assurance of quietness, inasmuch as the water tends to deaden sounds. Rather than deaden the sounds, however, the designer has sought to eliminate the cause of unnecessary noises by properly proportioning the weight of the valves, the spring pressures

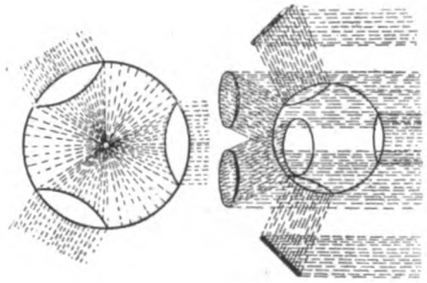
Digitized by Google

and, in particular, the shape of the valve cams. The cams and the cam shaft are forged integral and the cam faces have very small radii, which makes for quietness; the radii of the cam noses, however, are liberal, and ensure quick opening and closing, with large, unobstructed passages for the gases. Another of the distinctively up-to-date practices in use involves the construction of the intake and exhaust manifolds, which are cast integral, thus ensuring thorough warming of the unburned gases and a consequent partial cooling of the exhaust gases. The manifold itself, however, is separate from the cylinder casting, in order to eliminate the possibility of unequal distortion of the several cylinders.

Clutch Leathers Not "Finished Parts."

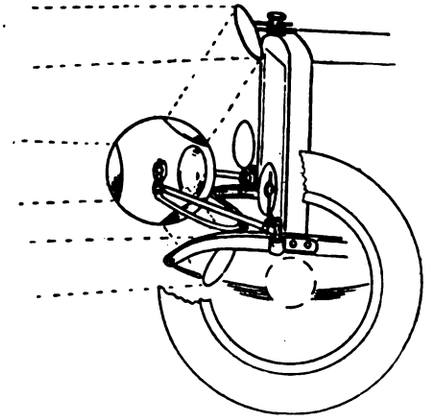
In sustaining a claim filed by Bolts & Brothers, importers of leather materials, the Board of United States Appraisers holds that strips of leather for use as "clutch leathers" are not to be regarded under the tariff act of 1909 as "finished parts of automobiles." The Collector of the Port of New York considered them such, and accordingly exacted duty at the rate of 45 per cent. It was his opinion that the strips were complete manufactures, ready for use.

The importers denied this and submitted expert testimony to the effect that the strips, before being fitted to the clutch cones, have to be soaked in water for twenty-four hours, trimmed down to fit, and made rough so as to incite friction. Attorneys for the Department of Justice failed to controvert the importers' testimony, although the board granted an additional thirty days for the purpose. Judge Fischer sustains the contention of the importers for duty at the rate of 15 per cent., under the provisions for "leather cut into forms suitable for conversion into manufactured articles." The Collector was reversed and ordered to reliquidate the duties.



To Repair Broken Battery Connections.

Without the proper tools and equipment lead burning is an impossibility, and even with all the requisites, unless the operator is proficient, not a little trouble is experienced. When the storage battery lugs become disconnected, if the operator is either inexperienced or without the proper facilities to burn them together, it is well to resort to autogenoous welding, which is really not so complex as the name seems to indicate and can readily be carried out by anyone who can hold a soldering bit. It suffices to clean the lead lugs thoroughly by scraping and apply a layer of lead amalgam, which is a mixture of lead and mercury. Pass the heated iron across the amalgam and the union is complete. Care should be taken to see that none of the melted lead drops into the battery or on the sealing material.



ONE BULB EQUALS FIVE LAMPS

At Least That is the Claim Made for the Diva Device—Headlight of Extremely Radical Design.

To make one lamp perform the functions of two, or, rather of five, has been the object of a British inventor in bringing out a lighting system which is by far the most unique of its kind that has been evolved in along time. Though the principal purpose of the new system, which is styled the "Diva," and is marketed by the Diva Headlight Co., of Bradford, England, is to eliminate the glare which with ordinary lights always has been a source of inconvenience and even of danger to the drivers of approaching cars, it has other virtues as well. For instance, it is claimed actually to increase the efficiency of the car to which it is attached because the shape of the lamp causes a draft of air to impinge on the center of the radiator where the action of the fan is least felt!

DIVA HEADLIGHT RAYS

DIVA SYSTEM IN PLACE

In its simplest aspect the new system consists of a spherical lamp which contains an electric bulb, preferably of six or eight volt size, though nothing is said of the candlepower, and a series of four mirrors. Set into the spherical shell are five lenses, one of them being directly in the center at the front and serving to direct the light rays forward, and the other four being so placed in the rear of the shell that they cause the light rays to impinge on the four mirrors which are attached to the shell by means of extension arms. When the lamp is lighted the shell becomes a veritable "ball of light;" by arranging the angle of the several mirrors the light may be directed at the will of the driver. Once set, however, the adjutsment cannot be changed from the seat.

One of the interesting features of the system is that by reason of the shape and focus of the lenses the rays given off are parallel, which, it is claimed by the manufacturer, is responsible in no small measure for the exceptional illuminative power of the system. In other words, the rays all are put to some useful purpose and are not wasted by diffusion upward and to the sides. Another interesting feature is in the construction of the special bulb which is supplied with the system. In it two metallic filaments are used and, contrary to usual practice, they are connected in parallel instead of in series. Thus, if one filament should become ruptured the other would continue to burn and the efficiency of the lamp therefore would be only partly impaired.

Though it might be supposed that rain or mud on either of the lenses or the mirrors would cause a serious loss of reflecting powers, it is claimed that such is not the case, the explanation given being that by reason of the superior shape of the reflectors and lenses and the utilization of all the light, even fairly large incrustations of mud have no appreciable effect. As may be seen in the accompanying illustrations, the lamp, with its mirrors, is intended to be attached centrally in front of the radiator, which quite naturally obviates the possibility of using the starting crank. To allow of the use of this necessary adjunct, however, the whole system is mounted on a swinging bracket and may be moved out to one side temporarily. In the newest form light, the lenses are so ground that rectangular instead of circular beams of light are projected.

Concerning Holes in Cylinders.

Locating a sand hole in a cylinder casting is not always a simple matter, and other expedients besides simple inspection must sometimes be resorted to, especially if the crevice is of "pin hole" size. The method most generally employed embodies the plugging of one of the inlets to the water jacket and the introduction of water under pressure through the other, when the hole can be easily located by the fine stream of water which will spurt out. If the hole is so fine that the water issues very slowly in the form of small drops, it is best to leave it alone, for it is certain that when the motor is running the hole will be still smaller. If, however, the hole is large enough to work a negative effect, a piece can be cut out of the water jacket large enough to permit a piece of iron to be welded into the flaw. The inside of the cylinder should then be touched up on a grinder to smooth down the high spot, and the opening in the jacket closed with a plate.

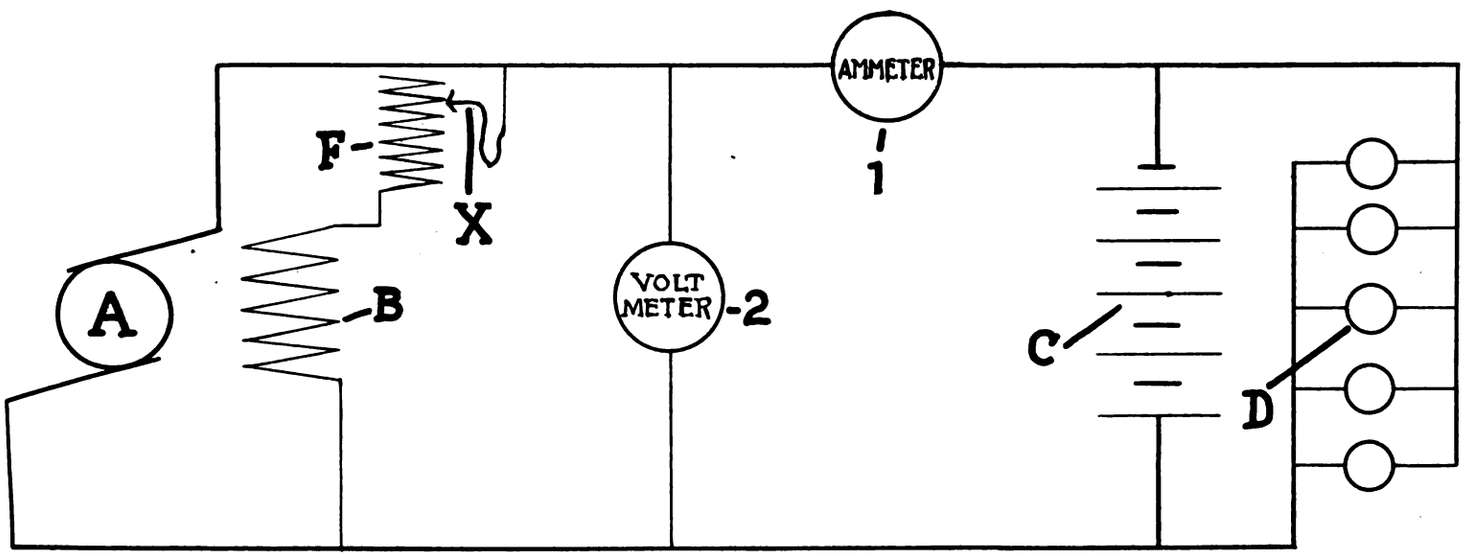
GOVERNING THE ELECTRIC LIGHTING SYSTEM

The Chief Problem that was Encountered and Overcome — Effects of Varying Speeds of Automobile Motors and Many Fluctuations of Battery Voltage and What They Entail—Two General Methods with Distinctive Variations that are Followed.



If the "lighting up" operations under the old system, with acetylene headlights, and oil side and tail lamps, had been confined to the simple striking of a single match and the illumination of one burner, it is doubtful if the newer order, the electric lighting system, would have come so rapidly into favor. When the conditions under which the lighting up operations are conducted are considered—a muddy road, a fitful breeze which seems to blow from all points of the compass at the same moment, several matches so impregnated with moisture by virtue of the damp night air that they might as well be headless, and three oil lamps one of which is covered with mud and two gas lamps to be lighted— it is not at all surprising that the electric system with its extreme simplicity and convenience of operation should be, colloquially speaking, "all the rage." Though the operation of depressing a couple of push buttons seems like the very acme of simplicity, this lack of complexity has only been attained after the expenditure of much time and thought on the part of the designer in the solving of such problems as the production of a constant voltage by a dynamo driven from an engine the speed of which constantly varies within very wide limits.

It is just here that designers and engineers found the greatest problem of all; to generate current is easy but to so govern the source of generation that the amount of current given off, and its voltage, shall remain constant within narrow limits has been the rock upon which such systems split.

Fortunately, however, there are many ways in which positive governing of the generator output can be effected—they are immutable laws in the science of electricity —and though it has required continual study and research positively to harness them to the needs of man as exemplified in the automobile generating and current storage system, which must be at once small, compact and sturdy, no small measure of success has been achieved. But the fact remains that the slow development of electric lighting systems for motor cars can be traced in the main directly to the one problem of insuring positive regulation of the generator.

The condition of the battery as to charge and discharge, and the number of lamps in use at any given time, obviously are factors in the maintenance of a constant voltage; the production of a suitable switch to disconnect the dynamo from the battery when the voltage of the dynamo is lower than that of the battery is of course a necessity.

Probably the simplest means of obtaining constant voltage from a dynamo driven from a variable speed motor is to limit the speed of the dynamo, voltage fluctuation taking place only when the speed of the motor is below that necessary to produce this maximum rotation of the armature. This maintenance of constant speed is readily attainable in several various ways, the most simple of which is the employment of a clutch either of the friction or magnetic type between the driven pulley and the armature shaft. It is evident that a dynamo which develops its full output at low speeds, or a high speed dynamo geared quite high in relation to the crank shaft, will produce a constant voltage over a great range of car speeds. The friction clutch is the type most generally employed, the relative position of the faces of the clutch being controlled so as to allow slipping or positive engagement at different motor speeds. This is generally accomplished by a centrifugal governor acting against a spring.

DIAGRAMMATIC SKETCH SHOWING METHODS OF VOLTAGE AND CURRENT REGULATION

The storage batteries generally used in conjunction with the car lighting systems have as characteristics:

(1) Low internal resistance.

(2) Practically constant voltage during charge or discharge at the normal battery rate.

(3) Approaching a charged condition the voltage rises abruptly, often necessitating an increase of between 25 and 30 per cent. in the dynamo voltage in order to maintain the charging rate normal.

These inherent characteristics influence the design of the governing apparatus. Where a constant speed generator is used it is quite evident that the batteries cannot overcharge, for the gradual rise in the battery voltage automatically cuts down the charging current, and the decided increase

Digitized by Google

in the battery voltage at the time when the battery is very nearly charged tends to render the charging current nil. Some provision for limiting the charging current when the batteries are discharged is of course necessary, for otherwise the very low internal resistance would allow of the passage of sufficient current to injure the battery plates to a greater or less degree.

In the lighting system made by Gray & Davis, of Amesbury, Mass., provision is made to prevent the increase of the charging rate of the battery above a maximum by shunting the field of the dynamo when the batteries are being charged; when the dynamo is carrying only the light load, it is compound wound. The centrifugal governor on the clutch allows the armature to rotate at 1,200 revolutions a minute, which armature speed is attained at moderate car speeds; constant voltage thus is assured, save when starting or stopping or driving in traffic. The automatic switch which cuts in the dynamo when the voltage has reached its limit, and out again when it has dropped below that of the battery, is actuated by means of an electro-magnet wound with differential coils. The coil which closes the switch is wound with coarser wire than the second coil, for it is designed to exert its pull on the full voltage of the dynamo while the latter works on the slight return current forced through the dynamo by the higher voltage of the battery as the dynamo speed is decreased. The dynamo and clutch are cooled by a current of air set in motion by fan blades cast on the face of the clutch discs. A battery of rather small capacity is used with this system, its usefulness being confined to the maintenance of the illumination at times when the motor is inoperative..

The choice of a battery depends primarily upon the conditions under which the system works; if the conditions necessitate burning the lights during prolonged periods with the motor at a standstill, a battery of rather large capacity is naturally essential. Under all conditions, however, the battery should be as small as to insure the relation between the periods of charge discharge being as nearly equal as possible, for it is only when such is the case that the battery is working under the best conditions.

In cases where the dynamo speed is not held constant, some means for maintaining a constant output must be resorted to. By far the most common method of decreasing the output is by changing the strength of the dynamo field; the methods of effecting this change of strength are, however, widely divergent; some are mechanical, some are a combination of mechanisal and electrical pure and simple.

No matter what form the governing apparatus takes in its final development, whether the field strength is varied by the insertion of resistance in circuit with it or by the action of a "bucking" field which tends to counteract the magnetic effects of the main field, the amount of variation is always proportional to (1) the change of the potential difference across the brushes of the dynamo or (2) the current output of the machine. In Fig. 1, A is a dynamo driven at variable speed; B is the field of the dynamo and is adjustable by means of the variable resistance F, and the slider X; C is a battery "floated across the line"; D represents the working circuit of lamps. 1 and 2 are ammeter and voltmeter, respectively, connected in the usual way so as to indicate the total output of the dynamo in amperes and volts.

If the voltmeter is watched the voltage during speed changes of the machine can be kept constant by altering the position of the slider X, thereby increasing the strength of the field as the speed of the machine decreases and decreasing the strength when the speed increases. It is obvious then that the amount of current flowing at any time is dependent only on the resistance in the line, or in other words, on the state of the battery and the number of lamps burning. This method of regulation is styled voltage regulation. It has been and is now used in many very successful lighting systems, and has two valuable functions: The charging rate of the battery is automatically decreased as the battery voltage is increased, and the current supplied to the lamps being a function of the voltage, is always constant. Broadly speaking, the voltage regulated system is in the same class with the system wherein the armature speed is controlled or limited, for in both systems the voltage is held constant, though the means employed are different. The one drawback, which, however, is easily overcome by properly proportioning the capacity of the battery to the time of operation of the lighting system, is that if the battery voltage is very low heavy currents are sent through the battery which are liable to work injury. This objection is very readily removed by simply supplying a battery of sufficient capacity to carry the lights for several hours without any very noticeable drop in voltage when the motor is inoperative.

While it is by no means impossible to render the movement of the slider automatic by means of a solenoid provided with a voltage, or fine wound, coil connected in shunt across the line, in practice much better results are obtained in systems wherein the number of moving parts has been reduced to the minimum. The general tendency where voltage regulation is adhered to is to render the dynamo self-regulating so that the voltage is held practically constant during speed changes, and this very desirable end is achieved without the aid of any movable parts, by taking advantage of the property of self induction which is present in all dynamos, and which tends to cut down the output as the speed of the armature increases. With the dynamo of ordinary design, however, this counteracting influence does not increase with as great rapidity as the voltage increases during a given speed increase, and as a consequence a rise in voltage is the result. By specially designing the machine it is possible to make the increase of self induction balance the increase of voltage and thus the latter is held constant. Such machines are now on the market and are manufactured by the Wagner Electric Manufacturing Co., of St. Louis, and the Holzer-Cabot Electric Co., of Brookline, Mass. In the latter system the effects of self-induction are increased by lengthening the tips of the pole shoes. In both systems the dynamos are shunt wound.

Referring to the figure again, it is obvious that by watching the ammeter, the variable resistance can be regulated so that the current output is constant, although the voltage necessary to maintain this constant current may increase or decrease according to the dynamo speed. This method of regulation is current regulation, and is used extensively in practice, the field strength being varied in various ways. The virtues of the system are many, chief among which are the constant current which is always supplied to the working circuit, and the constant charging rate which precludes the possibility of battery plate injury due to too high charging rates when the battery is in a discharged condition. As is the case with the voltage regulated machines, the general practice is to eliminate moving parts insofar as is consistent with good regulation; where moving parts are used they are made light so as to render the effects of inertia as small as possible. In the Rushmore system, designed by the Rushmore Dynamo Works, of Plainfield, N. J., the strength of the field is controlled by the current output without the aid of any mechanical devices whatever. The field magnets are wound with a main field coil, which is connected in shunt, and a "bucking" coil which is connected in series with the armature but is shunted with a coil of heavy iron wire. When the current is low the iron coil is cold and its resistance quite a bit lower than the resistance of the supplementary field coil; when the current value rises, however, the iron heats slightly and after having reached a temperature just below red heat its resistance increases very quickly. Being connected in shunt with the bucking field, the greater resistance of the iron wire coil forces more current through the supplementary field and the strength of the magnetic field thus is lessened.

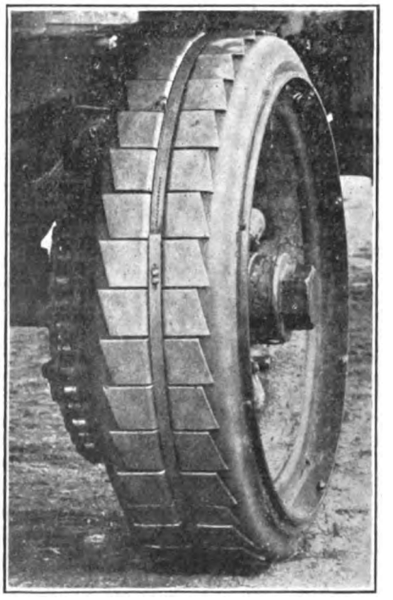
The Aplco, the product of the Apple Electric Co., of Dayton, Ohio, and also the system manufactured by the Remy Electric Co., of Anderson, Ind., are similar in that they both use automatic relays operated by current coils, which coils tend to pull an armature against the pressure of a spring and so introduce resistance into the field circuit. In both, the fields are singly wound. The resistances are made up of piles of carbon disks compressed by a spring, the pull of the electromagnetic coil

Digitized by Google

lessens the tension of the spring and consequently the current value rises.

The Ward Leonard system, manufactured by the Ward Leonard Electric Co., of Bronxville, N. Y., also has an automatic field rheostat, which, however, is novel in that there is but one step of resistance introduced by the current coil when a predetermined current strength has been reached in the line. When the current value falls below this predetermined value the resistance is shunted out. The Deaco system, which is also of the current regulated type, and is the product of the Detroit Electric Appliance Co., employs a permanent magnetic field which is either increased or decreased by a variable electromagnetic field, the connections of which are changed according to the current in the line. When the current value is small the electromagnetic field is connected in shunt across the brushes in such a manner that it assists the permanent field. As the current value rises the connections are first broken, then reversed with a resistance inserted so that the electromagnetic field is bucking the permanent field, and as the current value is still further increased the resistance is shunted and the action of the permanent field is counteracted by the effects of the variable field. The various connections are made and changed by the action of two electromagnets which act on two armatures against the tension of springs. By varying the tension of the springs the current output of the machine may either be increased or decreased

The Vesta Accumulator Co.'s system embraces a method of governing which is unique. Instead of governing the output of the dynamo, as is the case with all of the other governing systems extant, the governor of the Vesta system controls the ingress of current into the working and battery circuit. The armature shaft is fitted with a governor of the centrifugal type which introduces resistance in steps as the speed of the machine is increased. Thus the resistance of the line is increased as the voltage is increased and the current value in the line is practically constant.



Voltmeters That Indicate Wrongly.

On electric cars using volt-ammeters considerable trouble sometimes arises from the fact that the heads of the indicating pointers of the meters not infrequently drop off, and the pointers, relieved of the weight, indicate figures that are too high, leading the owner of the car to believe that the motor is drawing a heavier current than really is the case, or that the voltage is abnormally high for some reason which he may not be able to figure out for himself. It is quite an easy matter to overlook the absence of the pointer head, and if the vehicle should happen to be stalled for lack of current when the voltmeter indicated that there should still be considerable current available, considerable trouble might be caused before the real difficulty was unearthed.

Tire Armor That Serves Two Purposes.

Despite the efforts of the tire manufacturers, one of the serious items of expense in the operation of a motor truck is the cost of tires, and one of the great problems of motor haulage is the reduction of this expenditure. Closely allied to the tire problem is the problem of traction on slippery road surfaces, and it not infrequently happens that the means adopted in endeavoring to solve the traction problem serve to hasten the destruction of the tires. Not satisfied with attacking either one of these questions separately, the Post Tire Armor Co., of Cleveland, Ohio, has set itself the task of overcoming both difficulties at once; the Post tire armor, which has been evolved for this purpose, is shown in the accompanying illustration.

While the Post device is by no means

POST TIRE ARMOR

the first tire protector that has been made with metal plates forming the wearing surface, it is claimed that the method of fastening the plates to the tire is original and that it is effective—which counts for a great deal more than mere originality. Each of the steel plates has a depression formed in the middle, and when asesmbled on the tire these form a continuous groove around the wheel between the twin tires. In this groove is wound a strip of spring steel some 30 feet long and wide enough to fill the channel snugly. The retaining band is thin enough to be very flexible radially, permitting the necessary relative movement of the plates as they come under the weight of the load, but is so wide that lateral motion is prevented and so strong that it is said to be more than equal to any strains that may come upon it. The continuous tread formed by the plates takes the road wear, reducing the wear on the rubber itself to that which is caused by the comparatively slight friction with the smooth steel plates; the loss on the plates themselves from road friction is given as approximately 1 cent per mile for most machines.

In the matter of traction the Post armor would seem to be decidedly effectice, the projecting edges and corners of the plates sinking into the ground and giving a good grip in any material that is capable of affording a hold.

DeDion Universal Joint Development.

For the lower powered De Dion-Bouton cars of the latest type, notably the eight, nine and twelve horsepower models the manufacturers have evolved a new style of universal joint which partakes of the functions of both a universal joint and an Oldham coupling. Though the principle on which it operates is not exactly new, the mechanism is worthy of more than passing note by reason of its inherent simplicity and ease of adjustment. It consists essentially of two grooved sliding members completely enclosed in a tight box-like housing, the grooved members serving as terminals for the ends of the shafts which are to be flexibly connected. By reason of the novel construction of the device, the shafts may be moved sufficiently, in any plane irrespective of each other, to preserve the bearings of either from damage. Not the least of its noteworthy features is that while it consists of the minimum number of working parts wear can be taken up very easily and at little expense by merely replacing the sliding members which form the bearings of the squared shaft ends.

The same DeDion lower powered models which are equipped with the new universal joint also feature a new clutch which is perhaps not quite as new as it might be inasmuch as it is but a modification of the familiar three-plate De Dion clutch which for years has been one of the distinguishing marks of this famous foreign brand of car. The new clutch is really the old clutch made over and refined, the principal difference between it and the clutch which still is used on the higher powered cars in the line being that the center disk is faced with leather. As the leather is put on in flat segments it is quite easy to renew. Another of the advantages claimed for it is that owing to the large contact surface comparatively light pressure between the plates is necessary. As is the case with the metal to metal clutches used in the larger cars, no lubricant is used.

Heat That Causes Carburetter Troubles.

Fuel supply pipes never should be run in proximity with the exhaust pipe or close to the muffler. Copper being a good conductor of heat, "gasolene steam" or "gas locks" are liable to be formed in the lead, which will cause the carburetter to be fed irregularly. If the installation of either the fuel pipe or the exhaust pipe cannot be changed it suffices to cover one or the other with asbestos.

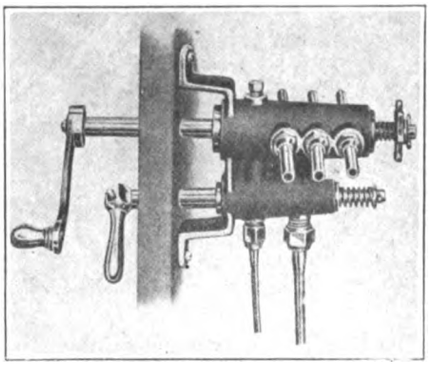
MOTOR STARTERS IN MANY STYLES

Special Model for Six-Cylinder Engines—Pumps Arranged for Operation by Hand or by Foot.

While most manufacturers are content to confine their energies to the production of a single type of device for giving the crank shaft of the engine its initial turns, the Auto Appliance Co., of Akron, Ohio, goes considerably further in that it provides a line of no less than four starters, in addition to a lamp lighter, a special priming and lamp regulating valve and a combined motor starter and lamp lighter. All the starters are of the acetylene type, but the details and the arrangement of the parts are worked out in various ways so that if the peculiarities of a car preclude the use of one model there is likely to be another that can be applied without trouble.



Model A is made with a gas-and-air pump mounted on the dashboard, under the hood, and operated by a handle on the driver's side of the dash, a set of valves mounted on the discharge end of the pump and the necessary piping from the acetylene tank and to the cylinders. To start the motor with the Model A outfit, the gas valve is turned on, the distributing valves opened by means of a handle on the dashboard and the pump handle pulled out and pushed in once for each cylinder of the motor. The valves then are closed and the gas turned off, when a touch of the button causes the spark that ignites the charges pumped into the cylinders. The gas pressure is regulated by a special regulating valve, the proportion of gas to air drawn into the pump thus being kept constant. A special type of Model A starter is provided, in which the pet-cocks on the motor can be used instead of the distributing valves on the pump, if the pet-cocks are suitably located. Model B differs from Model A only in the substitution of a spring-returned pedal for the handle for operating the pump. When not in use the pedal is held close to the dashboard by a hook. As in Model A, a special type is made for use in connection with the cylinder pet-cocks when this arrangement is possible.

Model C differs considerably from the other two, and, while not quite so simple, is so designed that it leaves the motor very little opportunity to refuse to start. It involves the use of a compressed air tank in addition to the gas tank; both are piped to a combined cut-off valve and mixing chamber mounted in the usual position on the dash under the hood. Just above the mixing chamber and cast integral with it is the distributing valve; both valves are operated by handles which project through the dashboard. The flow of gas and air is regulated by special regulating valves which operate automatically, the object being to ensure a proper mixture regardless of atmospheric or other conditions. To start the motor, the cut-off valve first is opened, permitting the gas and air to flow into the mixing chamber, when the turning of the distributing handle

"A-A" PUMP ENGINE STARTER

admits the mixture to the cylinders, after which the usual circuit-closing button switches on the igniting spark. A special construction of this model is provided for use with six-cylinder motors, which are somewhat addicted to stopping on dead centers. The distributing valve is arranged to be driven by chain and sprockets from a cam shaft. If the motor should fail to start because of its having stopped on dead center, pressure on a foot button opens a by-pass which allows compressed air to be distributed direct to the cylinders. No matter how the motor stops,

"A-A" DISTRIBUTER STARTER

there always will be a piston in such a position that the air pressure will cause a partial rotation of the shaft; and, as the cylinders already are charged with a good mixture, ignition and starting follow.

Model D handles acetylene gas only, injecting it into the cylinders, where it mixes with the air they already contain. The gas, under pressure governed by a regulating valve, as in the other starters of this make, is permitted to flow to the cylinders by pressure on a button on the dashboard, when pressure on the ignition button closes the ignition circuit.

In addition to these four models a "lighter-starter" is made, which consists of a pair of valves mounted together, with the usual dashboard control handles, one of which controls the flow of gas to the lamps and the other permits gas under pressure to enter the intake manifold of the motor, whence it finds its way to the cylinders. By keeping the starting valve open the motor may be run on acetylene as long as may be necessary; this feature is particularly desirable in cold weather, when it sometimes requires considerable warming up to induce a thoroughly chilled motor to run on its regular fuel.

The lamp lighter, which is made separately, consists of a needle valve mounted on the dash and controlled by a regular gas tank key, which is left open, acting only as a limit to the maximum flow of gas, and a second valve, which is used to shut off the supply to the lamps. The first quarter turn of the lighting handle closes an electric circuit which causes a spark at the gaps on the burners, and the remainder of the movement turns on the gas, the whole movement being half a turn. As the gas in the tank is used the regulating valve is opened to keep the maximum pressure at the lamp burners at the proper point.

For turning on the gas to the lamps from the front end of the car, and also for priming the motor with acetylene gas, a special valve is made which is designed to be attached to the frame of the car near the starting crank. A gas tank key is used to operate it.

Zinc Plate Might Save Radiators.

Outside of the reason commonly given for the use of nothing but pure water in the radiator—that is, the formation of scale—another and a very important reason exists. If two dissimilar plates are immersed in water in which a salt has been dissolved electrolysis is set up, which causes more or less rapid deterioration of at least one of the plates, the rapidity depending upon several factors, among which are the character and the quantity of salt dissolved, the material of the plates and the temperature of the liquid. The same thing happens with the radiator when care is not exercised to keep the water free from dissolved matter. The trouble could be entirely eliminated if all of the water used were distilled, but this, of course, is impractical. The method used on marine boilers for the elimination of the trouble is to suspend a zinc plate in the liquid, and it is not unlikely that the same treatment would also help on the motor car.

Hole That May Remedy Obstinate Leak.

When all other expedients to cure a leaky carburetter have been tried without avail, it sometimes suffices to drill a small hole in the cap over the check valve. This vent relieves the vacuum which is formed in the hole which serves as a plunger guide, which vacuum is formed by the plunger spindle when the valve is closing.

ELIMINATING THE LOSS IN BATTERY CHARGING

The Wastefulness of Common Methods of Charging Vehicle Batteries and a Suggested Method Whereby Conservation of Current May Be Effected—Facts and Figures in One Engineer's Experience That Prove Almost a Revelation.

As simple as is the charging of vehicle batteries, provided the operation is performed under proper supervision of duly qualified persons, how much simpler it would be if it were possible to plug in every battery on the same line, and, after a predetermined period had elapsed, disconnect them all, fully and properly charged. Which, of course, is the ideal, and therefore the unattainable—at least, under present conditions.

Standardization of battery capacities would be a step in the right direction and would simplify matters considerably. Unfortunately, however, attempts at standardization show no positive results as yet, though the tendency toward this desirable end is well defined. In the meantime it is up to the individual charging station to work out its own salvation. Which means, in the majority of cases, that a number of batteries of different capacities must be charged with the least possible loss of efficiency. The problem is not an easy one and is augmented by the fact that even when two batteries of the same capacity are sent in for charging they seldom if ever are in the same state of discharge. It is well known, of course, that the rate of charge of a given battery depends, within certain limits, upon its capacity, and that the time of charge depends upon the state of discharge in which it is put on charge.

In drawing attention to these matters in a paper which he read before the monthly meeting of the Electrical Vehicle Association of America on Tuesday, 26th inst., J. F. Lincoln advocates the use of separate motor generator sets as the one real solution of the problem. Before formally launching into a description of the "Lincoln Multiple Voltage System," in connection with which his maintenance and efficiency figures are a revelation, Lincoln recounts some of the disadvantages of of other systems, both direct and alternating current, the latter being used with the aid of a mercury arc rectifier, and his conclusions are more than ordinarily pithy.

"One of the most usual methods of increasing efficiency," he says, "is to charge two or more batteries in series on the 125-volt system. This will certainly increase the efficiency, as it charges twice as many cars with the same power expenditure as would be the case if but one car was charged on the same circuit. The difficulty with this scheme, however, is the fact that it is almost impossible in actual practice to get two cars of equal size of battery and of equal state of discharge that can be put on at the same time. It naturally follows, then, that the garage operator will take any two cars that happen to come in at the same time and put them on in series. One of these two cars will have had a greater discharge than the other, and, therefore, this car should be charged at a higher rate than the one which has been discharged to a lesser degree.

"Of course, this is impossible, and the car which has had the greatest discharge generally decides the rate at which the new charge will be put in. This results in a very rapid charge for the car already partially charged and also does not give it the tapering charge at the end which is so important for mileage and life. These two difficulties are so pronounced that in every high-class garage at the present time series charging for lead batteries is not used, and it would not be done in any garage if the owner of the car knew how harmful such charging is as it usually is carried out.

"With the mercury arc rectifier, of course, it is necessary to charge cars in series, this series sometimes being as high as five cars on a line. This system is just that much more destructive than having two in series, since it is commercially impossible to get five cars which are sufficiently alike in their discharge that the charging rate on all five cars can be made the same without harm to one or more of them. The cost of tube breakage is likely to be excessive, partly on account of inexperienced labor and partly on account of the frail nature of the tube itself. There is also added to this the annoyance and possible expense of a shut-down, necessitated by the tube breakage.

"On account of the wide diversity of voltages required, it will be necessary for the ideal charging system to deliver a multiplicity of voltages, these voltages to be but very little higher than the maximum charging voltage for any given battery. In series with the battery there should be placed a small ohmic resistance which will automatically cause the charging rate to decrease as the charging goes on, consequent on the rising voltage of the battery. It will be necessary to have this rheostat so arranged that any rate can be given the battery from 5 to 60 amperes without danger to the rheostat. It would also be necessary for the best practical operation to be able to read at one or more central panels the state of charge and the rate of charge of each battery in the circuit. With an outfit such as this, the smallest possible amount of power would be wasted, thus giving the largest possible efficiency. There would be no necessity for many operators, since there would be no shifting of cars to be done, as all readings could be taken from a central panel."

Descriptive of the "Lincoln Multiple Voltage Systems," which are made in a variety of forms, Lincoln says: "They are, primarily, when the current supply is alternating, a motor generator set, the generator giving two voltages, one of them 105 and the other 70. Direct connected to this generator is a small double commutator booster whose fields are excited from the 105-volt generator, thus giving it a constant excitation, two windings on the armature being so arranged that when turning at the speed of the motor generator set they will deliver five volts. With this outfit it will be possible to add to or subtract from the voltage of the main generator this five volts. In this way, the voltages actually given will be 65, 70, 75 and 80, also 100, 105, 110 and 115. Another feature of importance is the fact that positive or negative boost from this small booster will be taken from opposite sides; that is, from one side in the case of the 105-volt commutator, and from the other side in the case of the 70-volt commutator, so that the size of the small booster can be made very small in comparison with the size of the main generator.

"The majority of cars in operation at the present time have the following batteries: 24, 26, 28, 30, 38, 40 and 42 cell lead, and 24, 40 and 60 cell Edison. Ninety-five per cent. of all cars in operation at the present time have one of these combinations of batteries in them. The only other ones in use are a few old type machines, which have 12, 14 and 16 cells. The number of these, however, is so small that they can be practically eliminated. The voltages necessary to charge the batteries named above are as follows:

24 cell lead,	62½	volts
26 cell lead,	67½	volts
28 cell lead,	72½	volts
30 cell lead,	78	volts
38 cell lead,	99	volts
40 cell lead,	104	volts
42 cell lead,	109	volts
40 cell Edison,	74	volts
60 cell Edison,	110	volts

"It will therefore be plain that with this

Digitized by Google

charging outfit mentioned, all of the usual vehicle batteries now in operation can be charged direct from this multiple voltage system without a loss which will exceed a maximum of five volts, and which in actual practice will have an average of considerably less than two volts. This means a saving of from 2 to 50 per cent. over the single voltage system which is so often used. This also will allow all batteries to be charged in parallel, which is a very important feature. Another thing which is of especial importance is the fact that since there is a very small resistance in series with the battery, as the charge of the battery increases the charging rate will automatically taper off on account of the increasing of the battery voltage, thus giving automatically an ideal charge to the battery.

"Another feature is the consideration that on account of the very small loss in the rheostat, the size and cost of the charging rheostats can be made very small—very much smaller and cheaper than is possible to make a rheostat which must take care of voltage drops of from 40 to 50 volts, which would be absolutely necessary in the case of the single voltage system.

"Considering the relative cost of installation of the single voltage system and of the multiple voltage system comparatively, the kilowatt capacity of the multiple system to do a certain amount of charging is a great deal less than the kilowatt capacity necessary on a single voltage system. The reason for this is plain, since on a multiple voltage system practically all of the power generated is used as useful charging current and put into the battery, while in the case of the single voltage system a great part of the power generated is dissipated in heat in the charging rheostats. As an example of this we cite the following:

"The kilowatt capacity necessary to charge 10 24-cell and 10 40-cell cars at one time at their full ampere rate is, on the 'Lincoln Double Voltage System,' 26 kilowatts, while on the single voltage system the power necessary would be approximately 40 kilowatts, which, in other words, means that the 14 kilowatts out of this 40 kilowatts is dissipated in heat in the rheostats, while but 26 kilowatts is used in useful charging current. If in this example we had used a larger percentage of low voltage cars the difference would have been even greater in favor of the multiple voltage system; or, taking a concrete example, if two or the cars are 40-cell and 18 of them 24-cell, the capacity to charge them on the multiple voltage system is 26 kilowatts, while on the single voltage system it would be 50 kilowatts, meaning that 24 kilowatts out of the 50 kilowatts generated would be dissipated in heat in the charging rheostats. Another feature which reduces the cost in the multiple voltage system is the fact that since there is but a very small amount of heat to be dissipated in the charging rheostat, therefore this rheostat can be very small and have a much lower cost than if a larger amount of power was dissipated.

"The cost of charging in the usual garage is a very large item in the actual cost of operation. It is evident ,therefore, why it is that a great many garages insist that it is impossible to make an electric garage a paying proposition. It might be well to take an example of a certain garage to show just what the power and installation saving would be. It is already seen that the first cost of installation, on account of the smaller kilowatts capacity necessary, would be less than the single voltage system. Now let us consider what the cost of operation would be.

"There is a garage in one of the largest Western cities which has the following cars which are charged every night:

55—28 cell
22—24 cell
6—40 cell
18—24 cell
3—40 cell

"The capacity necessary to charge these batteries at their full rate, providing they are all put on at one time, would be, with the single voltage system, 260 kilowatts, and the cost of putting in a charge, providing the batteries of all these cars were exhausted, would be at a rate of 3 cents per kilowatt hour, approximately $58. The capacity necessary with the double voltage system will be 153 kilowatts, and the cost of putting a charge into these cars with the 'Lincoln Multiple Voltage System' would be $34. The cost of installation of these two systems would be as follows, including distributing panels, rheostats, wiring, etc.. 'Lincoln Double Voltage System' would be approximately $6,500, while on the single voltage system the cost would be $9,000, so that the operator would not only save 30 per cent. on his first investment, but he would also save approximately 40 per cent. in his total charging cost.

"At the same time he would be able to handle his garage with less help and would be able to take readings and taper his charges with less than half the attention which would be necessary with the single voltage system.

"If the supply current is direct instead of alternating, the problem is changed to a great extent. Almost all direct-current supply, if from the central station, is three-wire, giving 115 and 230 volts. The usual method of charging from this system is to either charge three cars in series on 230 volts, with the resulting harm of series charging, or to charge all cars in parallel at 115 volts, which means a large loss of power in the charging rheostat. It therefore becomes plain that there is a considerable chance not only for more efficient charging, but also for more efficient charging by getting the actual voltage which will be necessary for each particular battery. It is more easily taken care of, however, than it would be if the supply were alternating. The best possible scheme to do this would be to put in a three-machine balancer, cutting up the voltage into the following voltages: 75, 80 and 80. Then direct-connect to this the booster, so that the positive and negative boost can be given to any circuit. In this way it will be possible to get the following voltages: 60, 65, 70, 75 and 80. The 115-volt current can be gotten directly from the circuit from the neutral outside supply line. In this way extremely efficient working can be had, and also parallel charging. This means, in the usual garage, a saving of from 20 to 30 per cent. over the method which is usually used for this work and you also have the advantage of having a small and cheap rheostat and the added advantage that the battery will automatically taper its charge.

"In the case of the single car charging in the private garage, there are at the present time a great many rectifiers used for this work. The reason for the use of these rectifiers, as a general thing, is the fact of their very high electrical efficiency. There is not the slightest doubt that they are, electrically, a great deal more efficient than a motor generator set. In some cases this will be as much as 15 per cent. However, the cost of tubes for the usual private garage is so high that the small difference in electrical efficiency is more than over-balanced by the necessity for changing of tubes and by the inconvenience of shut-down. Another thing is that the rectifier can never be relied on to cut off at the proper time, unless the line voltage happens to be constant, which it never is in the usual outlying district when supplied with central station power. The cost of replacement of a 50-ampere tube is approximately $30. This includes the expressage on the tube and the electrician's time in replacing it. This is guaranteed by the company to last 600 hours, therefore the cost of operation per hour of the tube is 5 cents. The total power going through the tube on the usual lead battery is two kilowatts, which, at a 5-cent rate, costs 10 cents, or, with the addition of the 5-cent depreciation of the tube, the net cost of charging is approximately 15 cents per hour.

"The cost of the motor generator set to deliver the same amount of power would be 12 cents for this, taking into consideration also a difference of 20 per cent. in electrical efficiency, which is considerably more than the actual difference in electrical efficiency. The usual owner of a passenger or pleasure car is not nearly as much interested in a possible saving of a few cents one way or other as he is in the ability of the car to keep in operation. The occasional shut-down owing to the breaking of a tube means the loss of one or more days' use to him, which costs him considerably more than the few pennies' difference in the cost of charging."

RUSHMORE URGES SINGLE WIRE

Points Out Advantages of Grounded Return Circuit—Saving in Copper and Complication—Warship Examples.

"The brief note, 'Where Two Wires Are Not Necessary,' which appears in the last issue of the Motor World, touches altogether too lightly on what seems to us a most important subject," writes S. W. Rushmore, of the Rushmore Dynamo Co.

"Most people with but limited experience in electrical matters have the idea that gound connections must be avoided under all circumstances and are ignorant of the fact that the leading electrical engineers now recommend the grounding of even the highest voltage power transmission and lighting systems and that for the protection of life and property the neutral wire of all the great three-wire city underground systems is grounded.

"Most automobile engineers have to date insisted upon wiring their cars for electric lights on the insulated two-wire system, although we have argued that the grounded system is to be preferred on every point.

"1. It is ten times easier to insulate a single central conductor from ground alone than it is to insulate two wires in the same cable sheath from each other and from ground.

"2. With the large low volt lamps now used in headlights the voltage drop in the wiring is of great importance. If we use the same size wire and connect to the heavy car frame for return we save one-half the copper and at the same time cut the voltage loss in half.

"3. If we combine the two separate wires into a single central conductor we may still have better insulation with the same cable diameter, and, with the same investment in copper, cut the voltage loss to but one-fourth that with the same copper on the two wire-system.

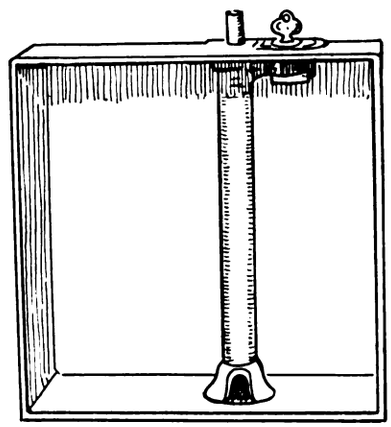
"4. It is generally conceded that the lamp base diameter that has been adopted for automobile service is altogether too small for the heavy currents employed since the perfection of the automobile lighting dynamo. It is too late to adopt a new base, but by using the rational single wire system there will be ample space for the heavy contacts demanded.

"We have for years made a specialty of electrical equipment for steam vessels and have installed our electric searchlights and also complete electrical plants on thousands of American and foreign-built ships. On all foreign ships, which constitute some 99 per cent. of all seagoing steamers, the one-wire system with ground return is used for all lighting and motor service and the foreign engineers argue, with perfect logic, that that system is not only safer, but, with thousands of tons of steel in the hull and frame of the ship, it is utter folly to use four times the amount of copper for the same service.

"On American-built ships the two-wire idea prevails, yet nine times out of ten it will be found that there is a ground on one side of the system. It is only human nature to leave well enough alone, and marine engineers almost never pay any attention to a ground until a second ground comes on. Then, frequently if the second ground is the heavier, the first ground will be "blown" off and things continue peacefully, with the ground detector showing on the other side.

"As a matter of fact, nearly all of the American ships are running on the one-wire grounded system, only the extra copper is a dead loss, and for the same investment in copper only one-fourth the maximum electrical efficiency is realized.

"In wiring an automobile one encounters on a small scale all the difficulties of wiring a steel ship, and the fact that the great 'Olympic,' together with practically every oceangoing steamer, is wired on the grounded one-wire system, should not be overlooked.



"There can be no question that the magneto must soon give way to the auto-sparker, taking current from the large car lighting battery, and an insulated, or 'groundless' ignition system would be regarded by most engineers as an absurdity.

"The point-to-point contact lamp base and socket now in use has been found totally inadequate and liable to frequent short-circuit. With the single wire system it will be very easy to employ connectors of simple male and female spring contact type of high current capacity.

"Several large car manufacturers have already adopted the grounded one wire system, and the leading tungsten lamp makers now supply the lamps in all candlepowers, with the base rim forming one terminal and with a single insulated central contact, and report the cost of manufacture to be lower than with the two-contcat type."

Locking the Gasolene to Prevent Theft.

While there are many possible ways of locking up a motor car that is left standing unattended, either in the garage or in the streets, there is no way that seems to appeal so strongly to common sense as that which will positively prevent the operation of the motor under its own power. This prevention of theft or the unauthorized use of a car is aimed at by the Ideal Auto Lock Co., of Detroit, Mich., in bringing out its device, the Ideal lock, which consists essentially of a gasolene shut-off valve which, when closed, is securely held in that position by a snap lock.

IDEAL GASOLENE TANK LOCK

The whole of the mechanism used, which is simple and not liable to get out of order, is installed in the tank, only the top of the lock and the push-rod by means of which the valve is closed being visible above the upper sheet of the tank. As the fuel is shut off at the bottom of the tank there is none in the pipes or in the curburetter when the car is left standing if the motor is allowed to run until it stops after the tank has been locked. To lock the tank it is only necessary to push down the locking rod; the key is required only for unlocking. No two keys are alike. The maker claims that the Ideal lock will fit any car and that it is not possible to force it with any tool.

Instrument That Answers Old Question.

When men first began to wonder how much more gasolene there was left in the tank, they satisfied their curiosity by poking a stick through the filling hole and noting how much of the stick was wet when it was withdrawn. There is no telling how much trouble has been caused by dirt and splinters from this primitive measuring instrument, to say nothing of the fact that it was a makeshift of the most pronounced type. A measuring instrument that is a development of and an improvement on the old stick idea has been brought out by the Jeannette Auto & Machine Co., of 12 South Second street, Jeannette, Pa. It consists of two guide pieces with a cork float between them. Pressing the guides toward each other at the top permits the cork to slide freely between the guides, and releasing nips the cork and holds it fast. To measure the gasolene, the "Safety gasolene rule," as the makers call it, is pinched at the top, inserted in the tank until it touches bottom, and the pressure released. The cork of course floats to the top of the gasolene and is held at that point while the rule is withdrawn. The total length of the instrument is 14 inches, of which 12 inches is marked off for indicating purposes.

While the instrument is marked off in inches, it is easy to arrange it so that it will read also in gallons by taking a series of readings with known quantities of gasolene in the tank and marking the scale accordingly.

HERE'S A SUBSTITUTE FOR WOOD

It is Composed of Inorganic Substances and is Styled "Asbestos Wood"—Its Properties Explained.

Professor Charles L. Norton, who is a member of the American Society of Mechanical Engineers and is of the faculty of the Massachusetts Institute of Technology, has perfected a substitute for wood the characteristics of which not a little suggest the possiblity of its application to the manufacture of automobile bodies and other parts which, in a great many cases, still are made of natural wood. The new material is described as "a refractory substitute for wood" by Professor Norton, the same designation serving also as the title of a paper which he read before the last meeting of the American Society of Mechanical Engineers and in which he fully described his product, which is claimed to be "practically incombustible, harder than natural woods, to have a transverse strength about two-thirds that of white pine with the grain, and, without being brittle, an elasticity less than that of natural woods."

In leading up to what he proceeds to describe as "asbestos wood," the material being made under his patents and developed from the application to certain mixtures of certain processes of mixing, pressing and curing, Professor Norton mentions first some of the earlier processes of fireproofing and waterproofing natural woods by way of pointing out the superiority of his new material over older methods and manufactures. Though the substances he describes in brief, and the processes, are more or less well known, his conclusions with regard to them are interesting, inasmuch as they tend to make plain the trend in the direction of obtaining a satisfactory substitute for wood for general use.

"Many of the earlier attempts," he said, "were made in the direction of altering the natural wood by some chemical treatment, so as to make it ignite with greater difficulty and burn more slowly and without much flame. These processes afforded a number of so-called fireproof woods. The principle underlying the treatment was usually one of two: First, the wood was saturated with a solution which, on drying, left in the pores a salt capable of giving off a gas when heated, this gas being of such a nature as to be incapable of supporting combustion. Phosphate of soda and tungstate of soda were used extensively for this purpose. With thorough saturation the protection afforded the wood and adjoining portions of the structure was by no means insignificant; specimens of wood treated with phosphate of soda have been in my possession for more than 10 years, and after 10 yearly tests show no signs of deterioration. Similarly, some specimens of wood and cloth treated with tungstate of soda in 1903 have shown little or no loss in fire resistance. The main value of such chemical protection lies in its diminishing the volume of the resulting flames. When once thoroughly ignited, the fireproof wood burns more briskly than the natural untreated wood.

"The second method of chemical treatment was one in which such substances as alum were used in order to supply a considerable quantity of steam from the water of crystallization and also to encase the pores of cells with solid refractory substance. A still earlier procedure was that of protecting wood from contact with a combustion supporting atmosphere by coating it with thin sheet metal, usually tinned iron or copper. For doors and shutters this was found very effective. More recently hollow metallic members for doors and trim and for furniture have been extensively used with a considerable degree of success. They are, of course, non-combustible, and under ordinary exposure keep their shape fairly well.

"There must have been from time to time in the last 30 years attempts to make use of boards composed only of refractory, inorganic substances. In general, such boards have been composed of some fiber and a cementing medium. The most popular fibers for this sort of experimentation have been asbestos and mineral wool, the cements used including about all the common cements of both the air-drying and the hydraulic types. Oxychloride of magnesium, the value of which as a cement was discovered some 50 years ago by Sorel, has been the favorite cement for experimenters because of its simple preparation, its quick hardening and great strength. For some reason, however, a large percentage of the oxychloride cement is variable in its properties and often defective. When mixed with sand or similar dense bodies, the oxychloride often is satisfactory for long periods, but my experience with mixtures of this cement with fibers, both organic and inorganic, leads to the conclusion that it is unstable and unsatisfactory.

"After much further study, two conclusions seemed inevitable: First, no homogenous inorganic substances are likely to prove satisfactory, but that a mixture of a fiber and a cementing substance is necessary to give wood characteristics to the material; and, secondly, a mixture of asbestos fibers with one or two cements (first, oxide of magnesium or calcined magnesia, and, second, calcium silicate and aluminate mixture) seemed more suitable than any other combination."

In describing his "asbestos wood" Professor Norton states that the "weight of the several grades per square foot, one inch thick, varies from 8 to 13 pounds." Inasmuch as perfectly dry white pine of the same thickness weighs approximately three pounds per square foot, and oak weighs nearly twice as much, it may be appreciated that there is considerable difference in weight. The other characteristics, however, offset this disadvantage.

"The transverse strength of 'asbestos wood' boards and the maximum stress is between the limits of 5,000 pounds and 10,000 pounds," he continued. "Test specimens 12 inches wide, 12 inches long and ¼ inch thick, broken by center load when supported on two edges with 11-inch span, broke, on an average, at 200 pounds load. Under the same conditions clear white pine broke under a load of 300 pounds with grain and 20 pounds across it. In some cases the equality of strength in both directions is of great advantage.

"The tendency of the material to absorb water varies between the limits of 4 per cent. and 20 per cent. This absorption is not of such a nature as to cause disintegration from freezing and the material is not injured by prolonged soaking in fresh water. Sea water tends to disintegrate it after a time, the magnesium salts in the water replacing the calcium of the cement. The coefficient of expansion varies with the temperature and also with the age of the specimen. It is small, being about 0.000004 at ordinary temperatures, diminishing rapidly at 700 degrees Fahrenheit, and becoming negative at 90 degrees Fahrenheit, where shrinkage occurs. The operations of boring, sawing and finishing are all somewhat more difficult with 'asbestos wood' than with the natural woods. It withstands scraping and rubbing much better.

"It is, of course, the fire resistance of the 'asbestos wood' which gives it its greatest interest. There is nothing combustible in it, and on exposure to fire nothing can occur except a gradual dehydration of both fiber and cement. Under prolonged red heat the boards become weakened, but for such exposure as occurs in fires in buildings the resistance is ample. For instance, a sheet of ¼-inch 'asbestos wood' may be placed over the top of an open furnace at 1,700 degrees Fahrenheit, the flame impinging directly on the lower surface of the sheet, and at the end of half an hour the sheet may be taken off and, while its lower side is still white hot, be plunged into cold water and then returned to the furnace for 10 minutes. It may be slightly warped and its strength probably will be diminished 25 per cent. or more, but it will still be sound and whole, and free from cracks or serious weakness. Fire tests have shown the ability of the material to withstand much longer exposure, but it is not suitable for linings for furnaces or kilns which are kept constantly at red heat. In some fire tests the paint on the outside of an 'asbestos wood' door 1¼ inches thick was not scorched after the fire inside had been burning at a temperature of 1,700 degrees Fahrenheit for more than an hour."

1,003,728. Detachable Rim Device for Road Vehicles. Alexander Flett, London, England. Filed Apr. 26, 1910. Serial No. 557,768.

1. A detachable rim device, comprising a tire-carrying rim, a fixed flange secured upon the wheel, a loose flange, seatings for said rim upon said flanges, said seatings acting to center said rim between said flanges, a bayonet-joint between said flanges, said bayonet-joint including slots having inner portions oblique to the plane of the wheel, a curved rack secured upon said loose flange, a pinion adapted to engage said rack, said pinion journaled at a fixed point of the wheel, means for rotating said pinion, means for locking said loose flange at any one of a plurality of positions, said locking means comprising a plate having teeth upon opposite edges and arranged in different pitch-relation and a cover adapted to inclose said rack and locking means, said locking means being attached to said cover.

1.003,743. Means for Starting Internal Combustion Engines. Gottlob Honold, Stuttgart, Germany. Filed Mar. 21, 1908. Serial No. 422,418.

1. In an ignition system for multicylinder engines, the combination, with a plurality of igniters, and a source of electrical energy arranged to supply current to the igniters, of a positively actuated circuit interrupter arranged to interrupt the supply of current to the igniters, a normally inoperative trembler circuit breaker and manually controlled means for rendering the trembler operative.

1,003,740. Spark Plug. Otto H. H. Heins, Edgewater, N. J. Filed June 16, 1909. Serial No. 502,491.

1. An igniter comprising a chambered tubular spark plug having an open and a closed end, a pole piece extending through the closed end and suitably insulated therefram, said pole piece bearing a terminal electrode in spark-producing relationship to said open end, and a blocking-out body of heat-resistant insulating material mounted on the pole piece behind said electrode and spaced away both from the side walls and the rear wall of the chamber within the plug, said blocking-out body being recessed on one or more end faces.

1,003,750. Starting Device for Gas Engines. Charles Francis Jenkins, Washington, D. C. Filed July 25, 1910. Serial No. 573,821.

1. In an internal combustion engine, the combination with a series of explosion cylinders and igniting devices for the same, of a non-explosion cylinder and a plunger therein, means for temporarily rendering the ignition device for one of the explosion cylinders inoperative, thereby converting the cylinder and its piston into a force pump, a conduit leading from the last named cylinder to the non-explosion cylinder to actuate its plunger, and means whereby said plunger when thus actuated may restore the inoperative ignition device to operating condition.

1,003,567. Automobile Power Motor. Clifford A. Woods, Plankinton, S. D. Filed Nov. 27, 1909. Serial No. 530,248.

1. An automobile power motor comprising a platform having inclined approaches to permit the conveyance of the automobile thereon, friction drums rotatably carried by the platform and projecting thereabove, rotatable means operatively connected with the drums for transmitting power, and an adjustable brace adapted for engagement with the drive axle of the automobile to position the drive wheels in engagement with the drums, said brace comprising a slotted rod carried by the platform, a pair of divergent arms slidably engaged with the slot and adjustably secured together at their upper ends and a clamp carried by one of the arms for engagement with the axle.

1.003,579. Pneumatic Cushion for Vehicles. George J. Bancroft, Denver, Colo. Filed June 7, 1910. Serial No. 565,619.

1. The combination with the axle of a vehicle and a spring thereof having a member extending below the axle, of a cushion composed of a lower frustum-shaped member having an exteriorly-projecting horizontally disposed part, an upper co-operating inverted dish-shaped member, and means connected with the lower spring member, passing through the frustum-shaped member of the device and forming a support for the inverted dish-shaped member, the latter being free to vibrate vertically with the spring and supporting means, and an endless pneumatic tube interposed between the inverted dish-shaped member and the frustum-shaped member of the device, substantially as described.

1,003,620. Combined Muffler and Air Heater. Edward Dudley Lewis, Elmira, N. Y. Filed Aur. 18, 1910. Serial No. 556,264.

1. A heater comprising an outer casing having an inlet at one end and an outlet at the other end, intercommunicating hollow sections arranged transversely of the said casing and having flanger edges in contact therewith, said flanges having openings out of alignment with each other, thereby forming a tortuous air passage: the end hollow sections being provided with an inlet and an outlet respectively for the heating medium.

1,003,619. Spring Wheel. Harry Laubersheimer, New York, N. Y. Filed Nov. 1, 1910. Serial No. 590,127.

1. A spring wheel including a yieldable tread constructed of separable sections, each of the said sections being formed at one end thereof with an undercut recess and at the opposite end thereof with an extension terminating in an enlarged head, the extension of each of the sections fitted within the recess of an adjacent section, and both the extension and the recess extending entirely from the top to the bottom of the tread section and having a uniform cross section so that the extension will slide within the recess in a radial direction with respect to the wheel.

1,003,621. Brake. Charles L. Lincoln, Bridgeport, Conn., assignor of one-half to Samuel H. Wheeler, Bridgeport, Conn. Filed Dec. 28, 1910. Serial No. 599,741.

1. In a brake of the class described, the combination with a drum, and a fixed support, of a brake band to encircle the drum, a stud carried by one end of the band, a bolt adjustably mounted in the stud, a link one end of which is pivotally mounted upon the support and the other end pivotally connected to the free end of the bolt, an operating lever one end of which is pivotally connected to the other end of the branke band and its intermediate portion pivotally connected to the ends of both the before mentioned bolt and link, and an operating rod pivotally connected to the other end of the said lever.

1,003,625. Odometer. Kendree Littlejohn, Pacolet, S. C. Filed May 23, 1911. Serial No. 629,034.

1. An odometer comprising an annular housing adapted to embrace the wheel hub, a registering device within the same and an actuating device for the register consisting of a circularly curved lever having a fulcrum within the annular housing and on one side of the center of the same, and an attached weight on the opposite side of said annular housing with respect to the center of the wheel hub, and means connecting said curved lever to the register.

1,003,768. Automobile. Henry Mayer, St. Louis, Mo., assignor of one-half to Frederick Mayer, St. Louis, Mo. Filed May 31, 1910. Serial No. 564,259.

1. The combination with the spark circuit of a self-propelled vehicle, of a steering-post provided with a recess or opening adapted to form part of said circuit, a steering wheel loosely mounted on said post, and a metallic locking member movably arranged on said wheel adapted to removably engage with said recess or opening to releasably hoid said wheel in operative engagement with said post, the graund wire of said circuit being electrically connected to said locking member and said circuit being completed or grounded through said post when said locking member is in engagement with said recess or opening, substantially as described.

1,003,795. Internal Combustion Engine. William Rabsilber, Brooklyn, N. Y. Filed June 21, 1909. Serial No. 503,294.

1. A system of fuel supply for internal combustion engines, consisting of the combination with a motor; of a reservoir for liquid fuel; a pressure tank in which is contained liquid fuel under pressure and at practically ordinary temperature; a heating coil connected with said motor and tank; means for heating said coil by the exhaust gases from said motor; mechanism for drawing liquid fuel from said reservoir and supplying it under pressure to said heating coil and pressure tank; means controlling the pressure at which the liquid fuel is supplied to said heating coil and pressure tank; and a valve-controlled conduit connecting said pressure tank and reservoir.

1,003,800. Rotary Explosion Engine. Pantaleon Michailowitsch Rodigin, Berdiansk, Russia. Filed June 22, 1910. Serial No. 568,415.

1. In a rotory explosion engine, the combination of an annular cylindrical casing, a shaft passing centrally therethrough, a disk keyed to said shaft, a plurality of pistons carried by said disk and adapted to rotate in said casing, a disk loosely mounted on said shaft and provided with a plurality of pistons also adapted to rotate in said cylindrical casing, a spring connecting said second named disk to said shaft, and spring-pressed abutments preventing the backward motion of said loose disk, substantially as described.

1,003,815. Protector for Vehicle Tires. Charles Scott, Baker, Ore. Filed May 10, 1911. Serial No. 626,324.

1. In a tire protector the combination

Digitized by Google

with a wheel and a tire therefor, of rings encircling the rim of the wheel adjacent each side thereof, an endless cable passing alternately around said rings and over the tread of the tire, clamping rings co-operating with the first mentioned rings, to prevent slipping of said cable, and means for preventing displacement of said clamping rings.

1,003,861. Starting Device. Lucian Hewitt Appelman, Clermont, Iowa. Filed Feb. 25, 1911. Serial No. 610,919.

1. In a starting device, the combination, with a mixing cylinder provided with means for securing it to the intake pipe of an engine and having also an air inlet valve and a laterally projecting tubular branch, of a fuel cylinder connected to the said branch and provided at one end with a tube which projects crosswise of the said branch and having also a valve for closing the said tube, and means for heating the other end portion of the fuel cylinder.

1,003,867 Door Signal. Leon Lipman Bories, San Francisco, Cal. Filed Nov. 7, 1910. Serial No. 590,991.

1. In combination with a door, an indicator mechanism, a door-actuated mechanism in the frame of the door, consisting of a tube having a longitudinal slot in the side thereof, a spring-pressed rod within the tube and having a finger projecting through said slot and a projecting end engaged by the door in closing, and an actuating wire leading from said finger to the indicator mechanism, whereby when the door is closed, the indicator mechanism will be actuated.

1,003,909. Internal Combustion Engine for Air Compression Purposes. Fred Edward Jackson, Williamstown, Victoria, Australia. Filed Nev. 21, 1910. Serial No. 593,498.

1. The combination, with a four-cycle, multi-cylinder internal combustion engine and a pipe common to the cylinders, for supplying the engine with gaseous fuel, of valve means interposed at a selected point in said pipe, and operable to cut off the communication of said pipe with a selected one of said cylinders and at the same time to establish atmospheric communication with the cylinder thus cut off from said pipe, and an air receiver adapted to be fitted to the cylinder thus cut off from said pipe and having a non-return valve.

Wants and For Sale

15 cents per line of seven words, cash with order. In capitals, 25 cents per line.

MILESTONES

in the march of progress denote advancement and we who wish to keep abreast the times must certainly keep alive to the ever changing situations. Otherwise we may soon be burdened with proverbial

MILLSTONES.

This is particularly true in respect to the purchase of automobiles and many hundreds of people annually suffer the consequences of ill-advised purchases from firms that engage in re-selling cars that never should have been on the market. The moral is

INVESTIGATE

for yourself very carefully before you buy a car, and especially a second-hand car. It will no doubt interest you to learn what else we may have to say on this subject. If so, write E. R. THOMAS MOTOR CAR CO., 1200 Niagara Street, Buffalo, N. Y.

A TREMENDOUS SACRIFICE—A professional lady leaving city, indefinite period, will sacrifice Ranier 5-passenger 4-cylinder 30-H. P. touring car; top, folding windshield, high tension magneto, extra shoes, tubes, tools, etc.; $300; warranted perfect running order. MRS. STOUTENBERGER'S CAR, 1075 Intervale Ave., Bronx, two blocks from subway, New York City.

GASOLENE Rumble Seat Runabout; would make exceptionally fine truck; $100; also Cadillac Delivery Car, $100, running order. BINGHAM'S CHAUFFEUR, 1075 Intervale Ave., Bronx, near subway station, New York City.

EXPERT CHAUFFEUR, motor boat operator and repair man wants work at once. Sober and reliable. Seven years' experience. Address, BENJ. SPRAGUE, 55 High St., Claremont, N. H.

LARGEST Dealers in Texas. High grade used automobiles for business and pleasure; also supplies. What have you to offer. COMMERCIAL AUTO & REPAIR CO., San Antonio, Tex.

FOR EXCHANGE—Two 30 x 3½ Airless tires; three 31 x 3½ Hartford tubes (seconds); one K. W. magneto with belt, model F. These things have never been used. LOCK BOX 134, Riverhead, L. I., N. Y.

HAVING decided to engage entirely in manufacturing, and to discontinue our automobile sales, accessory and supply business, a good proposition can be found by addressing BUSINESS, care Motor World.

EXTRA FINE Black Japan for enameling automobile lamps, radiators, fenders, etc. Will not crack, chip or peel. One coat covers solid. Air drying or baking. Have your dealer order today. THE COLUMBUS VARNISH CO., Columbus, Ohio.

AGENTS WANTED — To handle the $1,000 G. J. G. "Junior," racy, classy and specially designed chaseabout with 104-inch wheelbase, with a real 26 H. P. motor, Bosch magneto, Dorian remountable rims with 32 x 3½ tires, at a price of $1,000, which is a money-maker for the sales agent. Write for literature and discounts to G. J. G. MOTOR CAR COMPANY, White Plains, N. Y.

WANTED—Foreman for final erecting department. Large automobile factory in desirable location. Must be experienced man with executive ability, good character and energetic. BOX 201, care Motor World.

QUALITY RUBBER CEMENT—Best in the World—Hotter the weather the better it sticks. For repairing automobile, motorcycle and bicycle inner tubes and tires. This cement is unequalled. Send 20c. in stamps for two sample tubes. For terms and discounts, write HENRY E. EBY, Fernwood, Del. Co., Pa.

BARGAIN—$750 will buy a nearly new Mitchell 5-passenger automobile. New tires, Bailey tread, top, windshield and all accessories complete. Cost $1,500. As good as new, owing to short length of service. THE TRIUMPH ELECTRIC CO., Cincinnati, O.

LOZIER Touring Car, Model 7, 40 horsepower, good condition. JACOB HAGNER, 52 East Court St., Cincinnati, O.

ENGINE, 3½ H. P., Uncle Sam, Schebler carburetter and full equipment for 22 foot launch for sale or exchange for motorcycle. STEELE, 15 Maiden Lane, New York.

GARAGE FOR RENT—Most prominent corner in Bergen section of Jersey City; entrance on two streets; floor space about 170 x 50 on ground floor, 100 x 50 on second floor; brick building with elevator. Apply to owner, T. W. LEAKE, Bergen Ave. and Montgomery St., Jersey City,

---

SALESMAN—One who is now visiting automobile trade in general, to take side line. Liberal arrangements made. Attractive proposition. BOX 200, care Motor World.

FORD, Buick, Overland, E-M-F, Maxwell, Air-Friction Carburetors drive your cars 3 miles per hour on high. Much more speed, much less gas. Starts easy in cold weather. Satisfaction or refund money. AIR-FRICTION CARBURETOR CO., Dayton, Ohio.

HAVE YOU TRIED the new cotter pin tool; no more skinning of hands; 15 tools in one, at $1.00. For sale by E. M. WORDEN, Ladysmith, Wis.

ALL KINDS OF SUPPLIES and Tires at Bargain Prices. CHAS. DOWNING, 1779 Broadway, New York.

Empire 25

"The Little Aristocrat"

Price $850

Announcing

The Big Brother of the Famous Empire Runabout

The Empire 25 offers an astonishing and hitherto undreamed of value to those demanding a small car up to the standards of the biggest and highest priced automobiles.

This announces the new 1912 model of the Empire 25—probably the most splendid little car that has ever graced the American Automobile Market.

The Empire 25 has been aptly termed "The Little Aristocrat."

The Empire 25 is aristocratic in its clean cut, gracefully symmetrical and high grade design; aristocratic in its marvelous workmanship and finish; and it is "aristocratic" in its **performance,** which at once marks the Empire as the greatest masterpiece in small car construction.

Aside from superfluous power and excessive size, the Empire is in every other respect a miniature of the highest grade autos built. Such a **quality** at such a **price** has never been approached—**much less duplicated.**

A graceful car with body design following the general lines of cars costing seven times as much—the result of a prize competition entered by best known body experts in the country.

All doors **extra large,** to facilitate getting in and out, either side.

Big swell steering wheel—big artillery wheels with large hubs—big tires—a big 104-inch wheel base.

Following high grade car construction, the dash and cowl are of aluminum; the clutch is of 9-inch plates instead of 5, the kind commonly used in cars at this price, and the transmission is the same as used on cars up to 40 H. P.

Equipped with **High Tension Magneto,** the engine starts with half a turn.

Front axle and steering knuckles extra heavy; the idea of maximum strength, safety and reliability prevailing throughout, as in the construction of no other car at the price.

You can at once see that the Empire 25 sets a new standard for small-car value and at the same time introduces an **economy** of vast significance to an army of prospective automobile buyers.

SPECIFICATIONS OF THE EMPIRE 25

Motor—25 H. P., 3½-inch bore, 4½-inch stroke—cylinders cast in pairs.

Cooling System—Large radiator in conjunction with a belt-driven fan. Circulation effected by the thermo-syphon method.

Valves — Fully enclosed, adjustable for wear.

Lubrication—Constant level, force feed.

Ignition—High tension magneto, set spark.

Clutch—Disc clutch, dry plate type, Raybestos faced.

Control — Single lever, center control. Throttle lever above steering wheel. Clutch, service and emergency brakes operated by foot pedals.

Steering—Full worm and gear type.

Brakes—Two external, contracting. Two internal, expanding on rear wheels.

Transmission—Three speeds forward and reverse, selective type, mounted on annular bearings. Unit power plant.

Gears—That are silent even when shifting.

Rear Axle—Semi-floating type.

Front Axle—I-beam section, drop forged. The size of the steeirng knuckles would do credit to a car twice the weight of the Empire.

Springs—Three-quarter elliptic rear, semi-elliptic front.

Wheels—Selected second growth, artillery type. 32-inch, quick detachable rims.

Wheel Base—104 inches.

Body—Aluminoid steel, wood trimmed; fore-door, full vestibule, straight lines from front to rear, ample room in tonneau, seats wide and deep, buffed leather cushions comfortably slanted, inside handles on doors.

Frame — Pressed steel, channel section, dropped, giving low center of gravity and easier riding qualities.

Gasoline Tank—Capacity, 12 gallons.

Standard Equipment — Includes magneto, gas lamps, side oil lamps, tail lamp, tools, repair kit, tire pump, jack and horn.

Breaks Into New Field

The world is full of people who have long desired the kind of car-**quality** found hitherto only in cars **too dear,** both in **first costs** and in **upkeep.**

In "The Little Aristocrat" these people will suddenly awaken to find **realized** their dream of such a car as they wanted, and can now **afford to buy.**

Don't begin your investigation tomorrow. Begin it **today**—right now—at once. We want "The Little Aristocrat" distribution everywhere. Your name and address brings you our great and liberal offer. Write today.

Empire Automobile Company, Indianapolis, U. S. A.

The Annual Spring Number

OF

THE BICYCLING WORLD (FOUNDED 1877) and MOTOR CYCLE REVIEW

(April 27, 1912)

will contain information that will make it

A Complete Handbook of the Industry

Among the Leading Features Will Be:

1—A halftone and editorial description of every 1912 model of motorcycles and bicycles made in America.

2—A halftone of the president and sales manager of every American firm making motorcycles or bicycles.

3—A brief story of the condition and plans of the really live clubs.

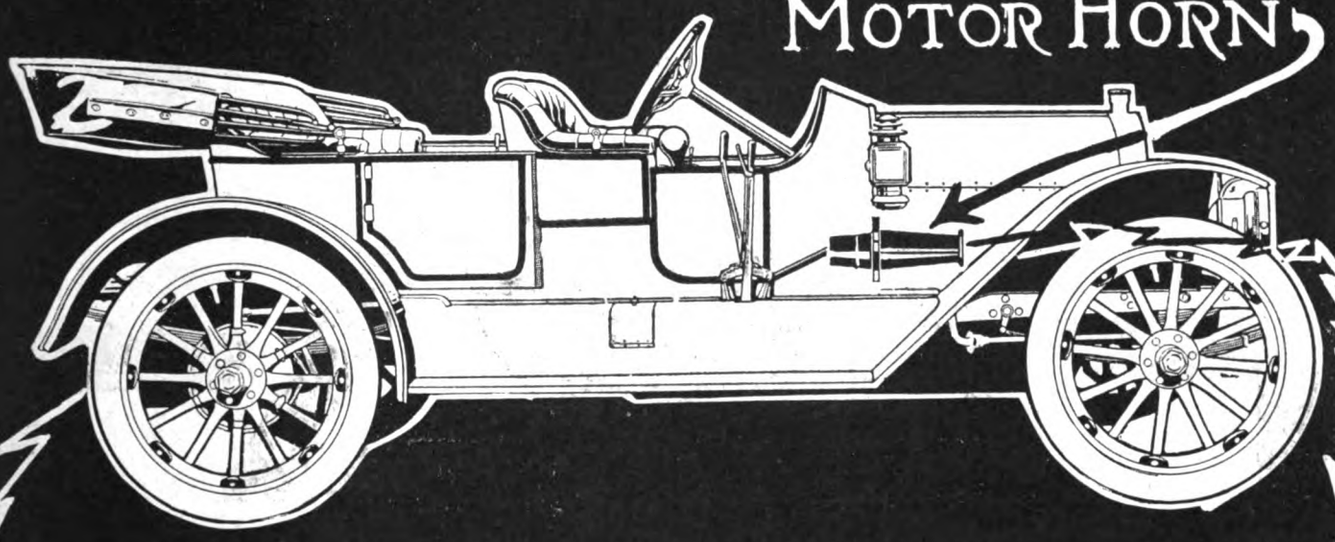
4—Cycling track records up to date, conveniently arranged for reference.

S—Several pages of historical matter covering the story of the "two wheeler" from the beginning.

6—A digest of all State laws governing motorcycles.

Present indications are that the Spring Number will contain over 200 pages, and will be illustrated by between 200 and 300 halftones and line cuts.

Nothing to compare with it has ever been published concerning motorcycles and bicycles.



Price 25 Cents Per Copy

All subscribers will, of course, receive a copy. Orders for extra copies must reach us by April 22nd.

The "Newtone" Motor Horn

NEWTONE—The Ultimate Warning Signal

In the Manufacture of the Newtone Motor Horn, Efficiency is the First Requisite and the Final Test

Newtone Torpedo Type

"The Mile-Away Motor Horn"

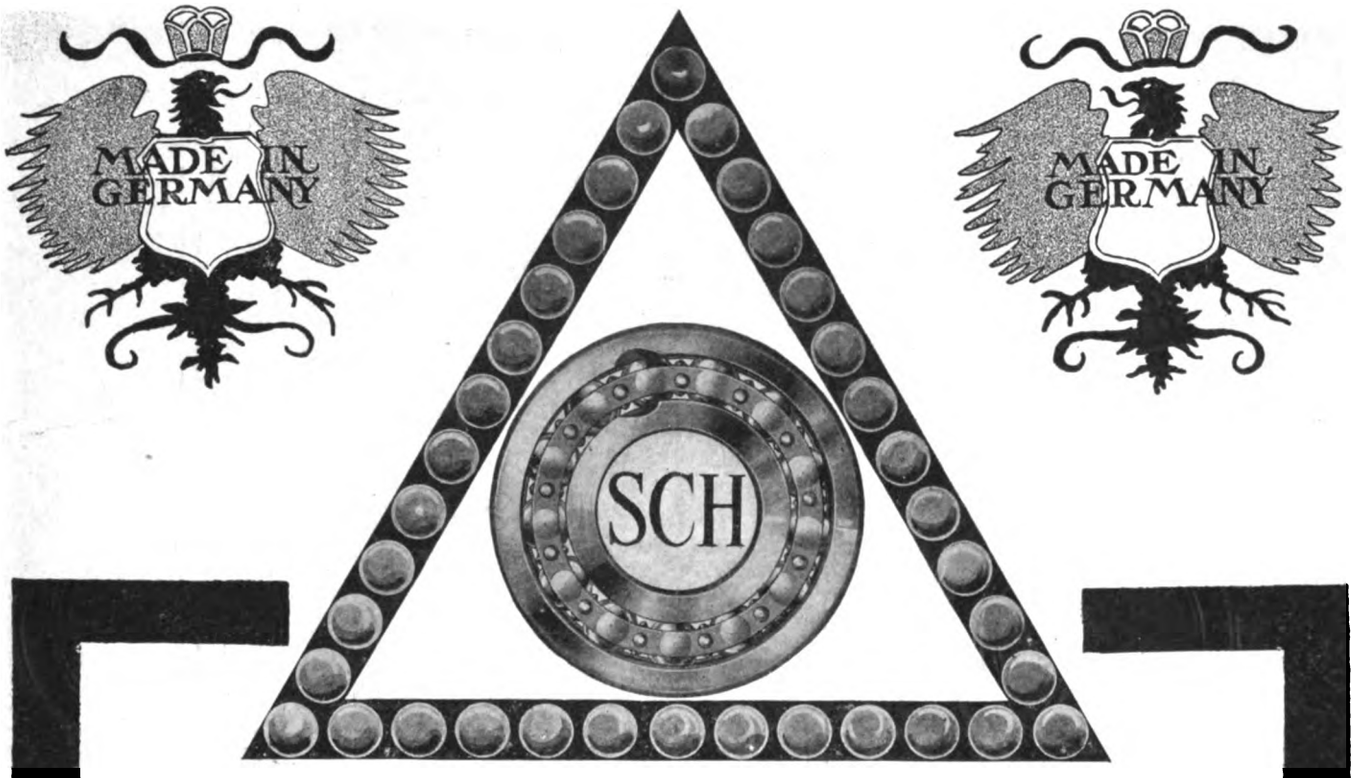
Price $20.00 Complete including Button and Cable.

Manufactured and guaranteed by a firm which for the past eight years has made and is still making over 80 per cent. of Automobile Horns now in use in the United States. Let us send one on approval.

Thousands Upon Thousands of

NEWTONE MOTOR HORNS SOLD

The increased demand for the Newtone Horn is due to its absolute efficiency in warning and economy in operation.



The Motor with the Hess-Bright Ball Bearing and imported self-lubricating brushes eliminates all oiling and cleaning.

The Chief Engineers of three leading American Automobile Manufacturers after a "Break-Down" Test stated that in their opinion the Newtone Motor Horn is the BEST warning signal made.

AUTOMOBILE SUPPLY MANUFACTURING CO.

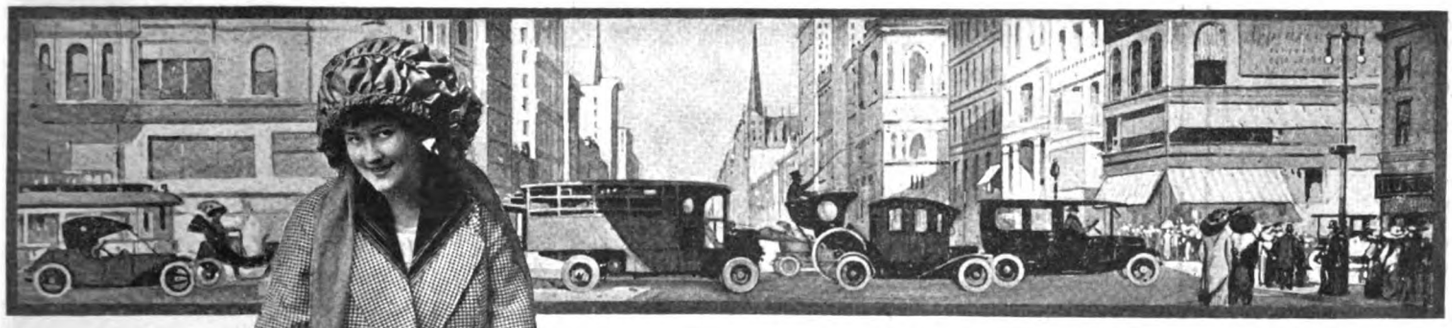
Does It Pay to Use Quality Bearings?

IN all moving parts the engineer's first thought is bearing efficiency—wherever ball bearings are practical no other form or type is considered.

But there is a vast difference in Ball Bearings. Schafer bearings, as produced by our master workmen at Schweinfurt, Germany, represent absolute perfection and accuracy in bearings.



Every ball produced by us is guaranteed to be accurate to within .0001 of an inch—this precaution is necessary to insure consistent and uniform carrying capacity. All Schafer balls and rings are made from extraordinary chrome steel of a special analysis. It is guaranteed free from blisters, air bubbles and spots.

Speaking of pneumatic tires, air is air, but you can't say the same of rubber—

still less can you say it of the rubber composition of which tires are made, which to most people simply means rubber. There is a wide choice in brands of tires, and extravagant claims can easily be made, but—

After all, the worth of a tire depends upon two things, viz.: A **knowledge** of rubber and a real **desire** to make good tires.

The mileage average of

Kelly-Springfield Automobile Tires

—better by a thousand or two than that of the average tire—shows our **knowledge** of rubber.

The reputation that you have known since 1895 shows how our **desire to make good tires** has been lived up to.

Let these be your guide posts in tire buying.

Kelly-Springfield Tire Company, New York and Akron, Ohio

1000 lb. Electric Truck

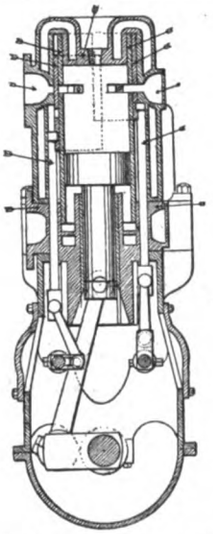
1896 K-D 1912

The Motor With the Sliding Crescent Valve

Knight-Davidson

The Sensation of the Boston Automobile Show



created more comment from the trade than anything else at either show.

Modern Engineering practice has placed the seal of approval on sliding valve practice—

Primarily because this modern conception eliminates springs, and noise, minimizes leaking, and increases port area.

The **CRESCENT valve** of the **K-D Motor,** fitting around the stationary piston wall affords a larger port area than any other poppet or slide valve on the market.

It is simpler and, consequently, better than any other valve construction known and is here offered to discriminating manufacturers, not as an experiment, but as a tried, tested and **proved** mechanical advance.

The **K-D motor** is **simple, silent, cools rapidly,** has the **simplest** oiling system known, will not **carbonize—AND**

Last and most important, will given on a given quantity of **fuel** more **power, speed and endurance,** unit for unit, than any other engine on any type of an automobile.

We want to present some **facts** to interested manufacturers that will be at least worth knowing—**facts** that if acted on, will add a large percentage of efficiency to the cars you, Mr. Manufacturer, may be turning out.

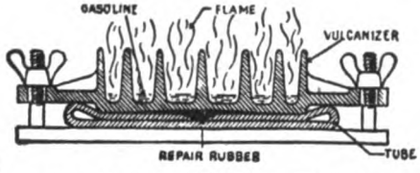
IMPERIAL VULCANIZER

A real money saver

IMPERIAL VULCANIZER

One ounce of gasoline, a little specially prepared rubber—and in 15 minutes you can repair a puncture in the inner tube



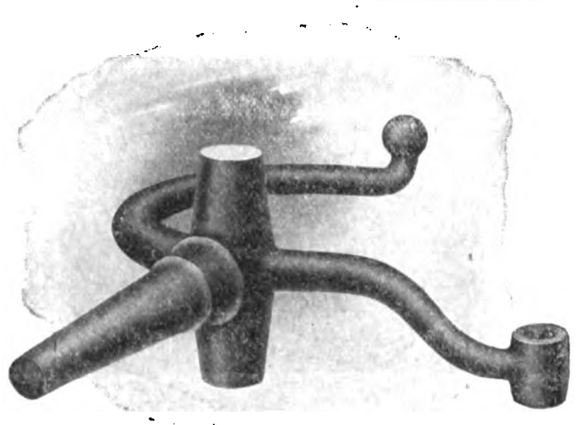
Patent Pending Nickel Plated

This is the vulcanizer you have been wanting all these years. Takes up very little room—weighs 3 lbs.—can be used wherever you happen to be when the puncture comes. No electric current—no steam—the gasoline supplies the heat—the vulcanizer is cleverly designed to automatically regulate this heat. The tube is easily and permanently repaired, practically

a new inner tube in 15 minutes

The price is only $3.50 for the kit with full equipment and enough specially prepared rubber for 40 punctures. Extra repair rubber costs only 25 cts. a roll, postage prepaid.

Sold on a guarantee of satisfaction—or money refunded. At your dealer's or sent by express.



A Word to Dealers—This new Vulcanizer is making a great hit with motorists. If you have none in stock write to us at once. Remember, we guarantee it in every respect.

Mr. Automobilist:

Your tire maker is very anxious to impress upon you the importance of

Tires Inflated to the Right Pressure

He insists that this is tire economy and

Saves You Money

How do you know what pressure you have in your tires? A

SCHRADER
UNIVERSAL
Tire Pressure Gauge

(Trade Mark Registered in U. S. Patent Office)

(Patented March, 1898—Other Patents Pending)

will tell the exact pressure in your tires at any time, day or night, by simply holding this Gauge to your Valve for a second. Its recording sleeve remains in place, showing the exact pressure in the tire so that the Gauge can be taken anywhere and read, at night to the front of the car into the light of the lamps. After the pressure has been ascertained the Indicating Sleeve can be pushed back into the Gauge with your finger. No catches or snaps to operate or get out of order. This Gauge is 2½ inches long over all, short enough to apply easily to the smallest diameter of wheel and can easily be carried in the vest pocket or the change pocket of your trousers.

Price $1.00 Each

Diamond Tires

We could build them cheaper
But We Won't

We would build them better
But We Can't

THE minute you begin to sell Diamond Tires you begin to profit by Diamond prestige, not only in your tire business but in your other departments.

¶ It is worth a great deal to be known as a Diamond dealer and we will help you make yourself known quickly and effectively.

¶ The services of high priced advertising men embodied in copy and cuts for all sorts of advertising are furnished to Diamond dealers without charge.

¶ In every way the Diamond policy is co-operation. Our interest in you is not governed by the number of tires you sell. Diamond service to dealers is as good as we know how to make it and it is the same to every dealer.

If you are not getting our little magazine for dealers you're missing something you don't want to. Send in your name today.

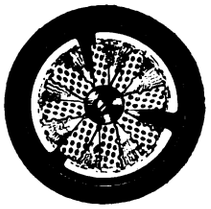
FEDDERS REAL SQUARE TUBE RADIATORS

No square tube "effect" or imitation, but made of individual square tubes. Of course the real square tube is better, that's why the others imitate it in appearance. They can't make the real article at the price.

Furnished with tubes staggered or Mercedes finish, as shown on cuts.

See Fedders Radiators on such cars as Packard, Thomas, Pierce, Haynes, Matheson, National, etc.

FEDDERS MANUFACTURING WORKS, Buffalo, N. Y.



5 to 7 YEARS SERVICE with a GLIDE

Season after season; not a new car the next year or the year after; nothing sacrificed to fads or notions —all built for endurance as well as beauty, strength and test of action, as well as ease and comfort in riding.

The Glide Catalogue for 1912 gives all particulars; tells why the Glide is the car of complete and elegant appointments; why it is, in all respects, the car of Style and seven years service. All Glide cars provided with Glide Self Starter without extra cost. Write for a catalogue and agents proposition.

REMY

Simple—Isn't It?

This little cam regulates the positive operation which makes the Remy the *best magneto made.* It is made of specially heat-treated chrome vanadium steel; case hardened and ground to size inside and out; fitted to the ground steel inductor shaft with square key. A few drops of oil a year makes it wear-proof.

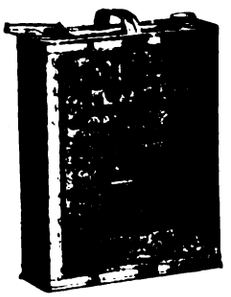
Polarine

The Best Oil for All Motors

When a car starts out lively in the morning and then shows signs of sluggishness later in the day, it usually means something is wrong with the lubrication.

Use **POLARINE** Oil and you will avoid two-thirds of all motor troubles.



POLARINE is the best automobile oil yet produced.

It gives the maximum lubrication for the amount used. It insures the least possible friction and wear, with full compression and power.

It leaves no carbon deposit.

It feeds freely right down to zero.

Look for the flat, convenient can—just fits in the tool-box. Ask your dealer.

Our free booklet tells all about the Polarine Brands, and contains many useful hints on the care of a car. Write for your copy today to any agency.

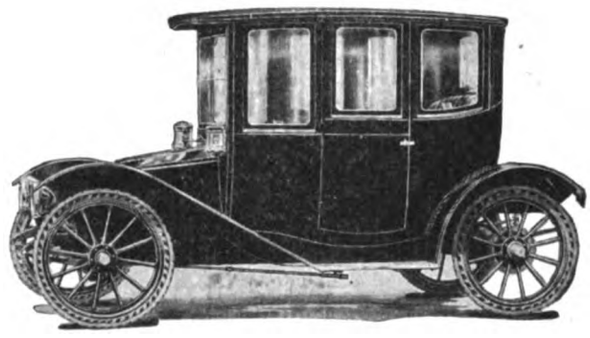
For Comfort and Elegance

in the fullest sense, select the Argo Electric. Its luxury is not alone that of handsome fittings and easy upholstery, but is built into the entire car from the silent power plant to the smallest detail.



Its beauty is not merely in fine finish but is inherent in its graceful low-hung design, its long, sweeping lines and its pleasing proportions.

THE ARGO BROUGHAM

is so distinctive in every feature that you must see a catalog for description and specifications to appreciate it. Shall we mail our new booklet—postpaid?

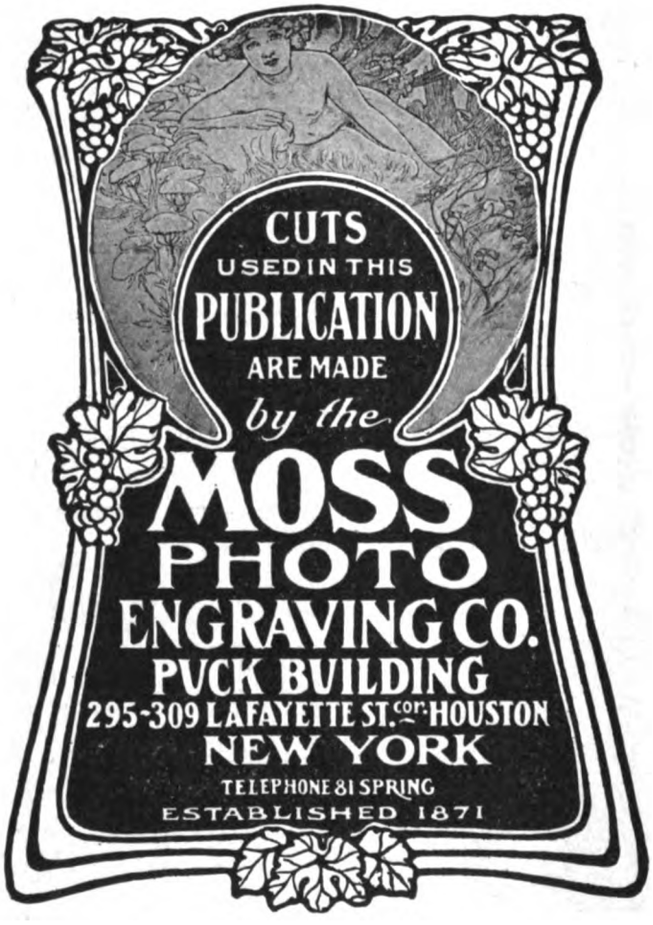
ARGO ELECTRIC VEHICLE CO., 1201 S. Jefferson Ave., Saginaw, Mich.

AGENTS AND DEALERS—The Argo Electric Wagon is another good business proposition. Ask us about both.

(Patented)

By Actual Test

The Sparks-Withington One-Piece-Blade RADIATOR FAN will deliver a greater volume of air with less horsepower consumption than any other fan on the market. Bonafide tests furnished to those interested.



With this assurance, and considering that we are specialists in fan construction where you are not, we desire the opportunity only to prove our claims, and, therefore, request your blue prints or a sample fan for estimate. Out of ten standards no doubt we can give you something without making special tools. That would mean a saving to you.

We will gladly test free of charge and submit report on fans you now employ.

Don't fail to write us when you are ready to consider 1912 contract.

B & L CASTER FRONT AXLE

Makes a Big Winner in Philadelphia

Our Philadelphia Agent writes it is a Great Success.

A. S. BURNELL, President and General Manager,
1346 Michigan Avenue, Chicago, Ill.

Philadelphia, Pa., February 28, 1912.

Dear Sirs:—The axle is a great success, is running fine. Have made several demonstrations and every one says it's the only front axle that ought to be allowed to go on the automobile, for safety, easy steering and perfect control. Will sell the majority of those I have demonstrated for. Enclosed you will find order for one axle to go on a Studebaker car, 1908 model, more orders will follow later. Send us a big cut for we are going to run a one-half page in our newspaper, we will advertise it right. We will equip at least one thousand cars this year. Our new garage will be at 1907 after March 12th, N. 23rd St. Circulars received all O. K., thanks for same. Rush the order for axle, as every one on a car will sell several more. Yours very truly,

H. SCHROEDER,
President and General Manager Lake Schroeder Auto Exchange.

Philadelphia, Pa., 1418 Blavis St.

AGENTS WANTED for all cities in the United States to put the B & L Caster Front Axle on old cars. Exclusive territory given to good men. Our axle when on a car proves that it is the only safe axle made. In buying a new car demand that it be equipped with the B & L Caster Axle. Write for Agency Proposition. Address:

A. S. BURNELL, Manager Chicago Branch, 1346 Michigan Avenue.

NORTH AMERICAN BUILDING
PHILADELPHIA

April 4th, 1912.

Messrs. MANUFACTURER, DEALER and COMPANY,
Every City, Everywhere.

Gentlemen--

EVERY MANUFACTURER CAN ESTABLISH A HIGH REPUTATION FOR THE CARS HE BUILDS BY USING ONLY THE BEST OF MATERIALS AND WORKMANSHIP IN THE MAKING.

EVERY DEALER CAN ESTABLISH A HIGH REPUTATION BY GIVING SATISFACTORY SERVICE TO HIS CUSTOMERS.

BUT--neither the manufacturer nor the dealer can maintain this reputation unless the cars they handle are kept in perfect working condition under all circumstances. ACCIDENTS CANNOT BE CONTROLLED BUT REPAIRS SUSTAINED THROUGH THESE ACCIDENTS CAN AND SHOULD BE CONTROLLED BY THE DEALER OR THE MANUFACTURER.

WE WILL GIVE YOU CONTROL OF THESE REPAIRS IF YOU CO-OPERATE WITH US.

TELL US YOU ARE INTERESTED and we will give you our plan.

Yours very truly,
ORGANIZATION COMMITTEE
By Ernest H. Greenwood
Secretary.

Hartford Pointers—No. 2

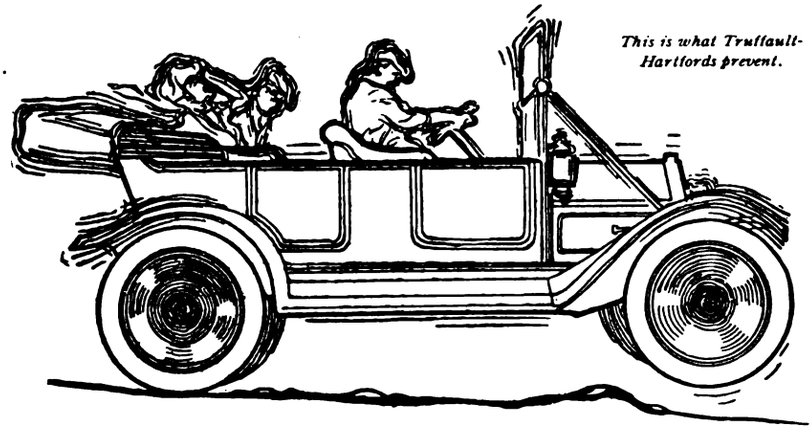
Uniform Speed—and Always Easy Riding

YOU motor for pleasure, and the greatest exhilaration is *speed*—not the speed of a racing car—but uniform, normal driving.

But what is speed without comfort—what is speed unless your car can take ruts and road obstructions without jolt or jar?

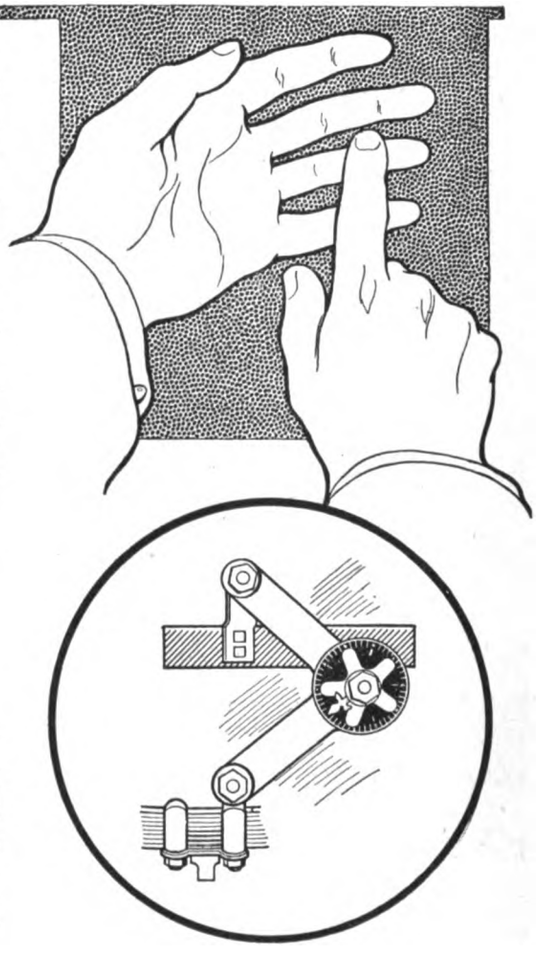
Slowing down for car-tracks, cross-walks and other inequalities, means lost time and loss of pleasure, too, yet it is the only safe alternative unless your car is equipped with the Truffault-Hartford Shock Absorber.

This is not an invention that exempts you from the dangers of reckless, haphazard driving, but a device that permits the maintenance of good speed over rough roads without the usual uncomfortable rearing and pitching of the car, and without the possible danger of a spring breaking. The



Truffault-Hartford SHOCK ABSORBER

acts as a retard to the violent and excessive action of the spring when the car strikes a rut or obstruction. Instead of the spring yielding to its inherent tendency of contracting with undue force, it comes together easily and gently. The recoil that follows is just as easy and regular, for the Truffault-Hartford exerts the same steady resistance to the upward movement as to the downward.



This elimination of jolt and jar accomplishes more than an improvement in the riding qualities of your car—it does more than allow for **better speed. It adds to the life of the engine and tires. For these reasons, motorists who have had the opportunity of noting how much the Truffault-Hartford Shock Absorber contributes to the riding and running qualities of a car, refuse to buy or use a car without this equipment.**

As further proof of Truffault-Hartford superiority, the fact is cited that there are now twenty-two leading car manufacturers in America who regularly include the Truffault-Hartford Shock Absorber on every car they produce.

Four Models—$60, $45, $25, $15.

This is what Truffault-Hartfords prevent.

Get in touch with a Truffault-Hartford dealer and have him explain to you the merits of this device. Our new illustrated catalog covers many vital points. Write for it today.

15 Years "Weeding Out" the Inefficient.

Since 1897 when we conceived the idea of the shock absorber (six years before the device was presented to the public at large) we had "weeded out" by costly experimenting, year after year, numerous other devices, including the *wedge*, *cam*, hydraulic, air-cylinder, strap spring, spiral spring, spring cylinder, etc. We have proved conclusively—that, so far at least, no other principle than rotary friction has come anywhere near to solving the shock absorber problem, and this is mentioned so that the public may take advantage of the knowledge gained at great expense during a period of 15 years.

10,000 Michigan Agents
Are Back of this Advertisement

They Are the Living Credentials We Offer In Support of Every Statement We Make

Thirty years ago we started to manufacture carriages. We commenced with a small factory and no agents.

Today we have increased our factory facilities a hundredfold and we have built up the most efficient vehicle selling organization in the whole world—ten thousand live, active agents to sell our products.

These agents know us and our work. They have confidence in everything we say. They are READY to handle any product of the Michigan factories—and put their individual reputation behind everything we produce.

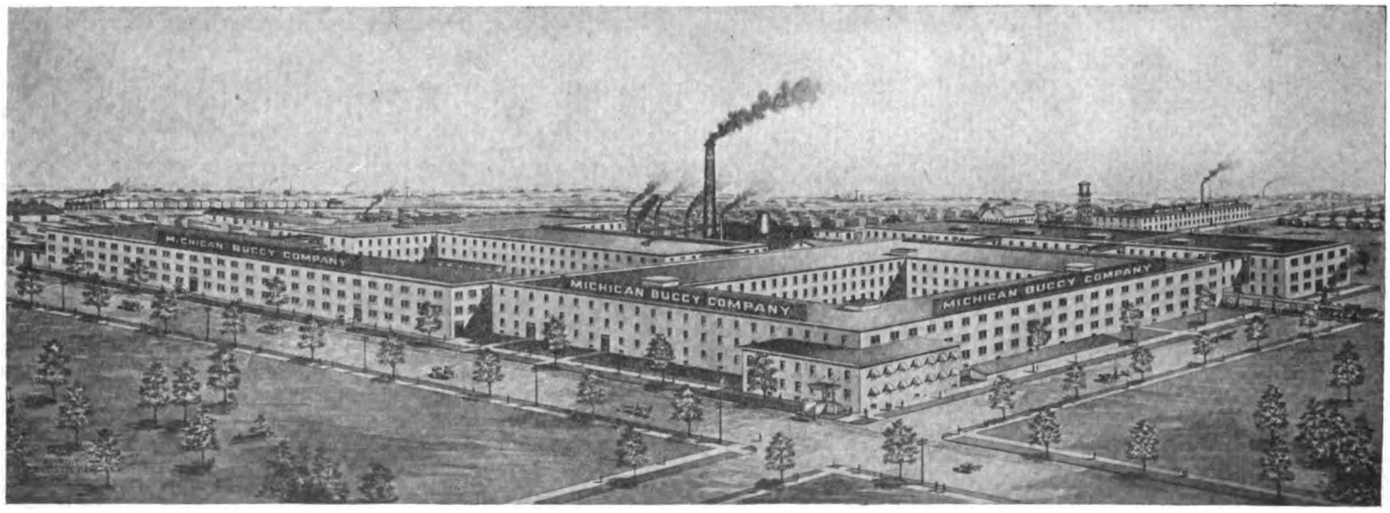
This enables us to manufacture our goods without selling cost. And thus saves this expense to the man who buys the goods.

The Birth of the "Michigan"

In 1909 we started to build automobiles. A simple announcement to our agents disposed of all the cars we could build. No expense.

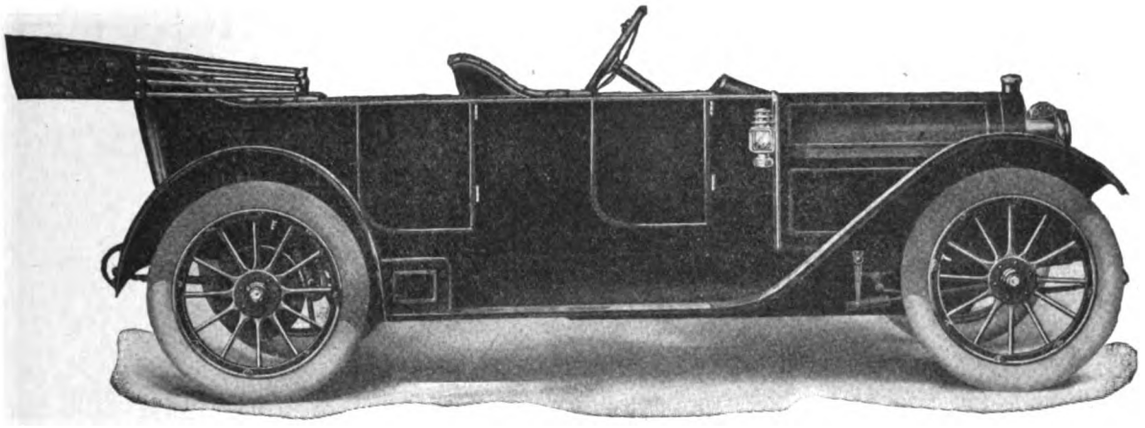
And thus it has been ever since. Our agents have absorbed our entire product. Thus for representation which has cost other manufacturers fortunes, we have paid not one cent. And that is why we undersell.

The Factory Behind the Car



Note the picture of the Michigan factories. They are a monument to our dealers. For all our success has come through our dealers—and their efforts in selling. We take to ourselves the credit of choosing these capable men and of being able to build with their help.

Our Complete Line



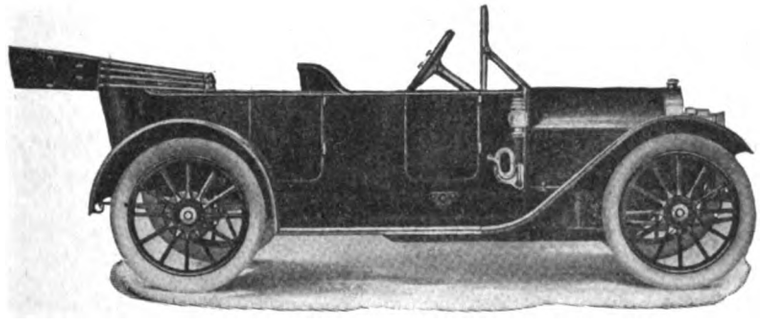
We call attention particularly to our Models K and H here shown.

Each is a masterpiece of its type. Each has met with the unusual favor of motorists and automobile experts.

We cannot in an advertisement do justice to our cars. We can merely note some of the many points. To realize the big values in our machines you must see them for yourself. Or get a catalogue, which describes everything in detail.

Digitized by Google

MIGHTY MICHIGAN "40," $1500



40 H. P. motor, 4¼ x 5¼", three bearing crankshaft. 34 x 4 inch tires, Demountable rims. Nickel mountings. 116 inch wheel base.

A Strong Guarantee

The Michigan Buggy Company backs up every car it turns out—with the broadest, most liberal guarantee that it is possible to place on a motor car. We do not guarantee the car for one, two or even six months. We simply say that if at any time the car proves defective, we'll make it right. And this guarantee means something backed by an old line concern of thirty years standing.

Big Features of Every Michigan Car

SELF-STARTER — We have tried out nearly every self-starter made. The one self-starter that our engineers found to be entirely practical we have approved for use on MICHIGAN cars. It is simple and easy to operate, nothing complicated. Very light and thoroughly dependable. We gave it thousands of tests under all sorts of conditions, and it proved itself absolutely efficient. Nobody likes to crank a car. What folks will insist upon in six months you get **now** on the "Michigan Forty."

MICHIGAN, MODEL H, $1400

The MICHIGAN "33"—Model H—at $1400 affords everything that the average family wants in a motor car save the surplus power and the extra room which comes with our Model K, the "Mighty Michigan Forty." It is completely equipped with self-starter—the best grade Mohair top that we can build, together with side curtains and dust cover—Zigzag Windshield. In fact, everything needed to jump in and drive away. Best materials are used throughout and the same materials go into the machine that we put into our MICHIGAN "40."

MOTOR—Absolutely noiseless in operation. Dust proof. Every moving part (except fan) enclosed. Long stroke, insuring greatest pulling power at low speeds, and utmost economy of fuel.

IGNITION—Tests of all kinds were made before we finally decided on the Briggs magneto. Not only did we find the Briggs the most efficient, but we felt that its strong guarantee gave MICHIGAN agents another big selling recommendation possessed by no other cars of equal price.

CLUTCH—MICHIGAN cars are equipped with clutch of Multiple Disc type. Can't grab—nor slip. A clutch that transmits a greater percentage of power to the rear axle than any other clutch on the market—bar none.

AXLES—Our three-quarter floating rear axle combines all the advantages of both the full-floating and semi-floating types, with none of the disadvantages of either. Hyatt High Duty roller bearings are used throughout.

WHEELS AND TIRES—We use genuine Shortsville A-grade wheels. Known everywhere for their strength. 1½ inch spokes, 12 to the wheel. MICHIGAN cars are overtired also—just to make sure that owners will not be bothered with that big bugbear of Motordom, tire trouble.

BRAKES — One square inch of braking surface for every eight pounds. Brake drums 14 inches in diameter, 2 inches wide. They are lined with Raybestos, making it impossible to burn them out.

FRAME — Extra strong, 5-32 inch steel. Four inches deep, 3½ inch flange. Its extreme strength makes impossible accidents due to weak frame construction, and does away entirely with body squeaks.

BODY—Here's where we have made big capital of our vast carriage building experience. Big and massive, yet graceful, and wonderfully suggestive of character and power.

COMFORT—Easy riding qualities secured by long wheel base, soft springs and luxuriously comfortable cushions. Appointments are perfect—such as you would expect to find only in cars costing $4000.

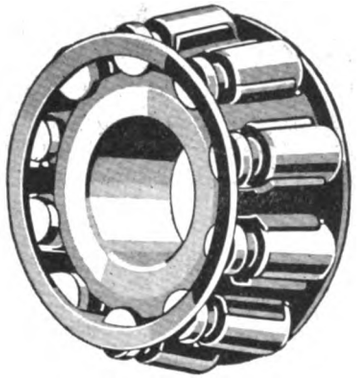
FISK TIRES

MR. DEALER:
HAVE YOU SOLD ANY ONE LINE OF TIRES FOR FOUR YEARS WITHOUT BEING CALLED ON TO MAKE A SINGLE REPLACEMENT?

Wm. S. McGregor has a salesroom and up-to-date repair shop in Daytona, Florida. He sells a good number of tires both to his regular trade and tourists. He believes in and sells Fisk Heavy Car Type Tires. IN FOUR YEARS HE HAS NOT MADE A SINGLE REPLACEMENT.

This is only just one specific instance. Another dealer in Illinois reports the sale of 150 FISK CASINGS WITH ONLY TWO CLAIMS FOR ADJUSTMENT. In both these cases the tires showed signs of having been run without sufficient air pressure.



Fisk Tires are made in one construction only—the famous **Heavy Car Type.** This produces a balanced casing that shows equal resistance to wear in all its parts. Our Pure Para Inner Tubes are what the name would signify. The average mileage of both is consistently high.

We would urge any dealer who has reason to wish to better his tire business by selling a new line to communicate with us. We are prepared to convince him that the rapidly growing popularity of Fisk Tires is based wholly on merit.

THE FISK RUBBER COMPANY
Department 23 **Chicopee Falls, Mass.**

Direct Factory Service in 35 Cities

There is big side pressure on the bearings in your car. It's the side pressure that pushes you along the seat when you steer around a curve.

"End-thrust" we call it in technical talk. And it comes full force on your front-wheel bearings.

Momentum makes the car tend to go straight ahead. When you steer to the right there's "end-thrust" to the left.

TIMKEN
TAPERED ROLLER BEARINGS

The rollers of Timken Bearings carry maximum load and stand the greatest shocks because they do it along their entire length instead of at points as with balls.

And they take end-thrust too, because the rollers are tapered and revolve about a tapered cone, inside a tapered cup.

The stress of load is a constant stress except as it suddenly increases with every hard jolt.

End-thrust comes as a plus stress on top of load and shocks.

Their tapered rollers give the Timken Bearings wonderful ability to meet all the stresses and all the shocks whether they come from the top or the side. Or whether they come from *both top and side.*

This is another of the many reasons why Timken Tapered Roller Bearings are used by the great majority of pleasure and commercial car builders in the wheels of their cars.

It will interest you to learn how many of the cars most familiar to you ride on Timken Bearings. They are named in a booklet "The Companies Timken Keeps." Write for it.

The Timken Roller Bearing Company
Canton, Ohio, U. S. A.

No Manifold Starter at any price is better than this at - $10

The Valentine MANIFOLD STARTER and Gas Lighter

And in addition to a manifold starter for only $10 we also include an electric gas lighting device that enables you to light your lights from the seat.

Remember, please, that there is no other manifold starter on the market at twice or three times the price of ours that is any better—most of them are absolutely inferior. And then we throw in the lighting device for good measure.

By a manifold starter is meant a starter which carries acetylene gas into the intake pipe or manifold with the dying revolutions of the engine as the engine is stopped.

No such device as the Valentine manifold starter and gas lighter can be purchased for less than two or three times the price of ours—$10. Nevertheless the Valentine has no superior.

WE BELIEVE THAT $10 IS ENOUGH TO PAY FOR ANY MANIFOLD STARTER, SO THAT'S WHAT WE CHARGE.

The Lighter Alone is Worth $10. You Get Lighter and Starter, Both for the One Price, $10

DEALERS :

We have some very fine territory to allot. If you will push this proposition get in touch with us.

Our lighting device alone will bring you many times $10 worth of comfort—to say nothing of the starter.

This is practically the only manifold starter that will allow you to run your engine on the magneto on acetylene gas without tearing the starter to pieces or holding down some spring or valve. If you run out of gasolene and are equipped with our Manifold Starter, just turn on the gas and let the car run.

We positively guarantee the Valentine starter and lighter. If you don't like it return it and we'll gladly refund your money.

J. H. Valentine Co., Syracuse, N. Y.

Enclosed please find $5. Send me a Valentine Starter and Lighter, on receipt of which I'll pay the additional $5. This order is based on the understanding that if, after 30 days' use, I do not like the Valentine Starter and Lighter my money will be refunded upon the return of the starter and lighter.

and here is the only 100% efficient Starter that doesn't foul your plugs

Self HANNA Starter

The Hanna Self Starter was the first acetylene starter on the market. Today it is the only 100 per cent. efficient self starter that does not soot and foul your plugs—because it is the only self-starter that accurately and scientifically measures and mixes your gas.

The Hanna Self Starter puts a scientifically correct mixture of acetylene and air into your cylinders when you are ready to start. Not the night before or two weeks before, but when you are ready to start. As a result it cannot help but start your engine.

There isn't any guess work to it. Not only does the Hanna Self Starter provide a 100 per cent. efficient self starter, but it provides the most economical starter. The measuring device does away with any excess of gas. It also thoroughly scavenges all the conducting pipes and valves by forcing clean, fresh air through them back of the gas. This assures perfect working of the starter indefinitely.

There are no moving parts in this starter to become loose, wear out or rattle. It weighs less than four pounds and is easily installed.

Sold under an absolute guarantee of satisfaction. If you don't like it send it back and we'll refund your money. The price is $35 for a four-cylinder car, $40 for a six.

Send $10 with order and we'll ship immediately.

American

American Axles

American

In axle manufacture, as in every other phase of motor car construction, there is a standard beyond which it is impossible to go.

In bevel drive axles, the word *American* implies the topmost height of axle development.

In worm and gear construction, the word "Lanchester"—proved beyond peradventure by ten years of drastic use on all types of motor driven vehicles—stands for that which is beyond betterment.

The association of the two names, *American* and Lanchester creates a double guaranty.

In the manufacture of axles, *American* now typifies the very best in both fields.

American Axles—either bevel or worm drive—can be furnished for cars weighing up to 4,500 pounds and to 60 horsepower.

Annular ball bearings are used throughout, with ample and adequate thrust bearings. Hubs may be equipped with either the annular or taper roller bearings.

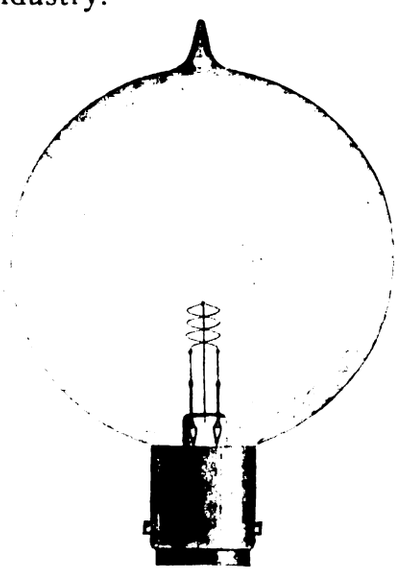
Does Anybody Question, for a Minute, the Superiority of Electric Lights?

They did once, but that day is long past.

What has made electric lighting possible and electric lights a practical proposition?

THE MAZDA LAMP



developed in less than four years from a crude and unsatisfactory product to the strong and highly efficient type shown below.

The human element is a big factor in Mazda lamp making. Each lamp must be handled by operatives whose highly-developed skill has been acquired by making lamps—thousands of them.

At the Federal Miniature Lamp Works operatives who make lamps today, are those who have grown up with the industry.

FEDERAL MAZDA

Look For The Label

FEDERAL MAZDA

Look For The Label

This is the headlight lamp. Notice the filament and its position in the bulb. This construction and shape of filament accomplishes two things—strength and the greatest number of light rays given off from a source of smallest area. Getting much light from a small "point" of radiation means that the reflector will gather and **project** a more brilliant and penetrating shaft of light.

The man who uses Federal Mazda lamps—look for the label—will be **sure** he has lamp construction which is the highest development yet attained in lamp making—his lamps will be uniform, each lamp or lot of lamps will be as good as previous ones—and every lamp will combine strength, high efficiency and long life.

Over 500,000 lamps have been placed in service. This means a large replacement business which should be handled by supply dealers, makers of brass lamps and lighting systems, battery makers and automobile manufacturers.

Reo the Fifth—$1,055

It Took 25 Years to Build It

By E. R. Olds, Designer

I have spent 25 years in building automobiles. Reo the Fifth is my 24th model.

I have watched every improvement, all the world over, from the very start of this industry.

I have had actual experience with tens of thousands of cars, under every condition that motorists meet.

All I have learned in those 25 years is embodied in this car. And I know of no other engineer in the business who builds cars as I build this.

My Precautions

What I mean is this:

The need for infinite care, for utter exactness, for big margins of safety is taught by experience only.

Countless things which theory approves are by use proved insufficient.

Splendid cars fall down on little points. The maker corrects them. Then something else shows unexpected shortcomings.

Perfection is reached only through endless improvements. It comes only with years of experience. Were I buying a car I would want it built by the oldest man in the business.

For Example

All the steel I use is analyzed, so I know its exact alloy.

The gears are tested in a crushing machine with 50 tons' capacity. Thus I know to exactness what each gear will stand. I used to test them, as others do, with a hammer.

I use Nickel Steel for the axles and driving shaft, and make them much larger than necessary. These parts can't be too strong.

I use Vanadium Steel for connections.

One after another I have cut out ball bearings, because they don't stand the test. I use roller bearings — Timken and Hyatt High Duty. There are only three ball bearings in this whole car, and two are in the fan.

I test my magneto under tremendous compression, and for ten hours at a time. My carburetor is doubly heated—with hot air and hot water. Half the troubles come from low grade gasoline, and this double heating avoids them.

I insist on utter exactness, a thousand inspections, tests of every part. As a result, errors don't develop when the car gets on the road.

Costly Care

I give to the body the same care as the chassis, for men like impressive cars.

The body is finished in 17 coats. The upholstering is deep. It is made of genuine leather and filled with hair.

The lamps are enameled. Even the engine is nickel trimmed. I finish each car like a show car.

The wheels are large, the car is over-tired. The wheel base is long, the tonneau is roomy, there is plenty of room for the driver's feet.

All the petty economies which are so common, are avoided in Reo the Fifth.

My Level Best

This car embodies the best I know. It is built, above all, to justify men's faith in my designing.

Not one detail has been stinted. Not one could be improved by me if the car was to sell for $2,000.

Reo the Fifth marks my limit. I will yield my place as the dean of designers to a man who can build a car better.

Center Control No Side Levers

In this car I bring out my new center control. All the gear shifting is done by moving this handle less than three inches in each of four directions.

There are no side levers, so the entrance in front is clear. Both brakes are operated by foot pedals, one of which also operates the clutch.

This fact permits of the left side drive. The driver may sit, as he should sit, close to the cars he passes—on the up side of the road. This was formerly possible in electric cars only.

The Little Price

The initial price on this car has been fixed at $1,055. But our contracts with dealers provide for instant advance.

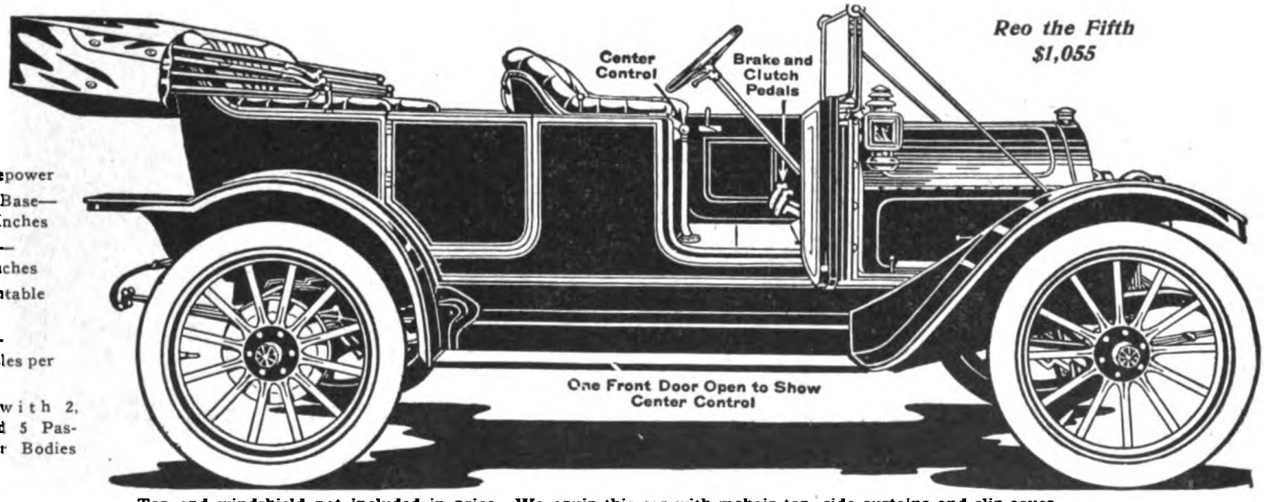
This price, in the long run, I regard as impossible. It is based on maximum output, on minimum cost for materials.

We have a model factory, splendidly equipped. Out output is enormous. We have spent many years in cutting cost of production. And this year we save about 20 per cent by building only one chassis in this great plant.

We can undersell others, and always will. But the present price is too low under average conditions. I am sure it must be advanced, and those who delay must expect it.

This car will never be skimped, while I build it, to keep within an altruistic price.

You Can See It In a Thousand Towns



We have dealers in a thousand towns. When you write us for catalog we will tell you the nearest.

Write today for this book. It pictures the various up-to-date bodies, and shows all the interesting facts. The Roadster type sells for $1,000.

Never was a car in all my experience made so welcome as Reo the Fifth. Men miss a treat who fail to see this car. Address

A Complete Line Of JD SPARK PLUGS 75¢

JEFFERY-DEWITT-CO DETROIT, MICH.

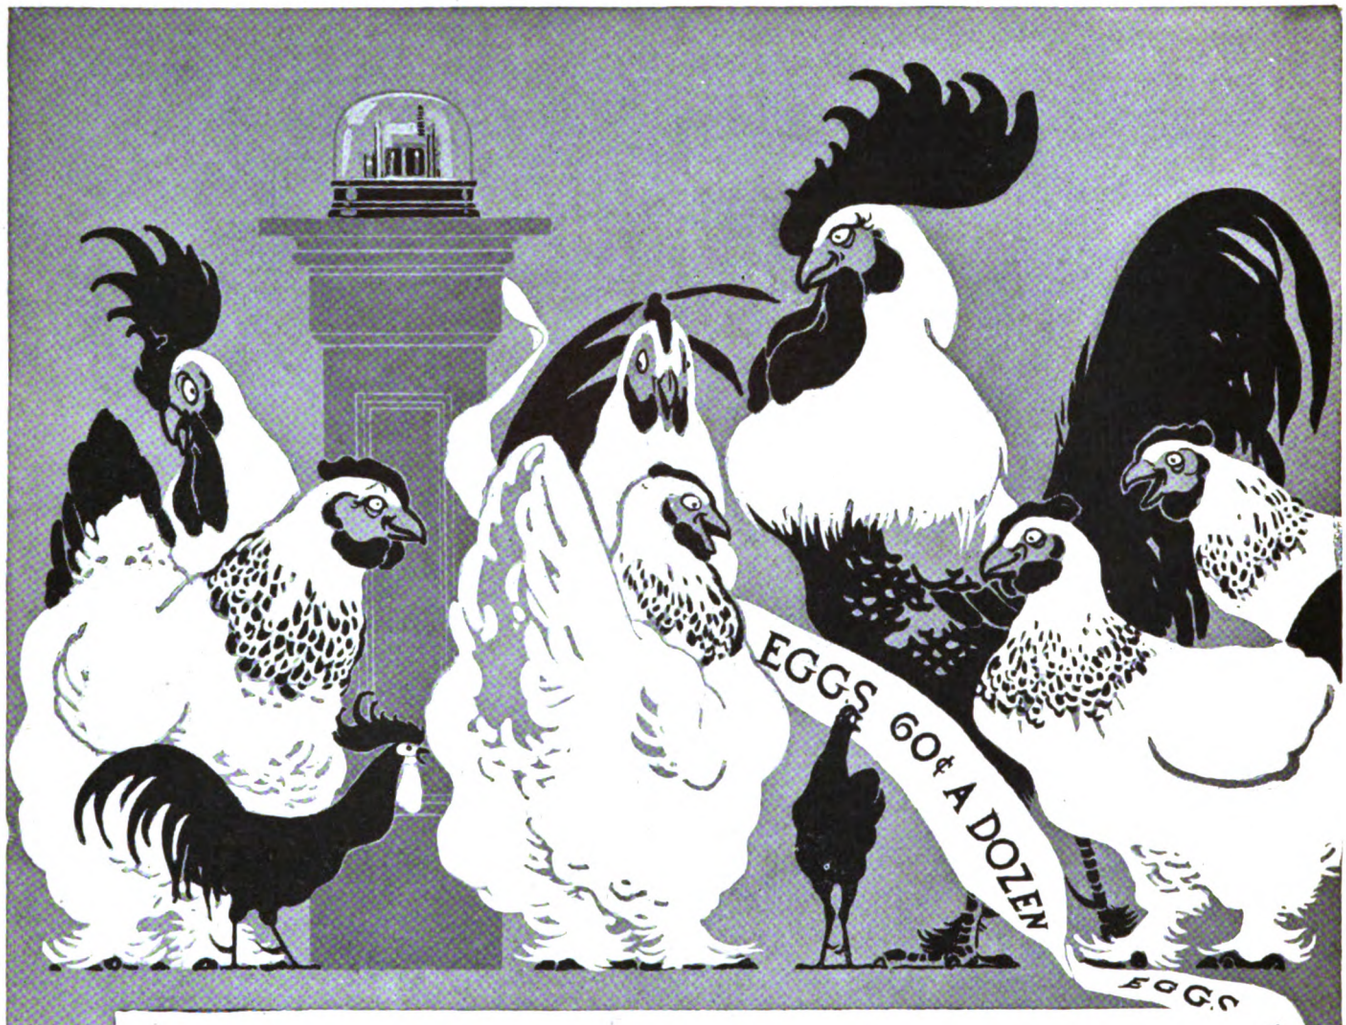
Efficient-Durable Economical

Made With Science

Sold On Honor

"Your Money Back or a New Plug if You Are Not Satisfied"

We can guarantee our "J. D." Spark Plugs because we know they are as near perfection as care and skill can make them, together with unrivaled facilities. From bushing to porcelain they are manufactured complete in our own plants—we buy no parts and depend on the open market for nothing except raw materials. We could not possibly buy any parts that we would be willing to back with that big guarantee we put on our goods—nor could we sell an assembled plug of this quality at so reasonable a figure.



When you buy a "J. D." Plug you are buying the only plug in the market that IS made complete in the one plant—the only plug that the makers can guarantee with absolute knowledge of every detail of the construction, including every step in the porcelain, even to importing the clays and other ingredients.

We have carried our scruples so far that we have made a model pottery all our own, and in it we make the "J. D." porcelain that heat cannot affect. No other porcelain is good enough for the "J. D." Spark Plugs.

You can get these Spark Plugs in three types—Petticoat, Closed End and Conical. If your dealer hasn't the kind you want—we will forward prepaid upon receipt of price—75 cents.

When Hens Don't Lay, Up Goes the Price of Eggs

When your grocer asks five cents *each* for eggs, he doesn't give you a bit better product than when he charges twenty cents a *dozen*. *Summer* eggs are just as good as *winter* eggs. The difference is in the *quantity*, not in the *quality*. The poultry man has the same overhead expense on each hen. But he has to charge *more*, because her output's *less*.

The *Stewart Speedometer* output is *always* large. *Eighty* per cent of the speedometers made are *Stewarts*. The price is *small* because the output's *big*. If we didn't make so *many*, it would cost as much as *any*.

Magnetic principle — jewel bearings — wearing parts hardened and polished — open dial — large figures — easily read — absolutely accurate — 100,000-mile season odometer — 100-mile trip register, can be reset to any tenth of a mile. Guaranteed for five years. Strongest flexible shaft, drop forged swivel joint, noiseless gears.

"ALWAYS ON THE JOB."

Speedometers, $15 to $30
Clock Combinations, $45 to $70

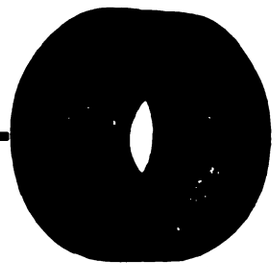
MAY WE HAVE YOUR LAYOUT

Of Bearing Installation?

¶ We can save you money, time and trouble—in other words, show you a short cut to satisfactory bearing installation.



¶ The successful use of New Departures in 60% of the motor cars manufactured in this country proves that the quality of this American made bearing has been well established.

¶ This fact also constitutes a good reason why you should send us your layout and give our engineering and sales departments an opportunity to place our proposition squarely before you.

¶ Our engineering department is highly specialized, not only for the production of superior ball bearings, but for giving to the trade expert co-operative service.

$850 Now Buys a Car of Real "Class"

Empire 25—the "big brother" of the Empire Roadster—invades the field with striking new characteristics. With the efficiency of the highest type cars and with the splendid lines of $5000 cars, "The Little Aristocrat" presents wonderful new opportunity.

Empire 25

"The Little Aristocrat"

The Big Brother of the Famous Empire Runabout

Here is a marvelous little touring car.

It is called "The Little Aristocrat" because it is **aristocratic**—both in **appearance** and **performance.** It is its appearance that makes this car distinctly different from all other cars built to sell at the price asked for the Empire 25.

A glance at design and specifications will indicate with what accuracy we have followed the general lines of cars in the $5000.00 class. We do not exaggerate when we say that "The Little Aristocrat" is a $5000.00 car **boiled down.** It is a small edition of the highest priced **quality** car that money can buy.

The same exclusive grace and beauty—the same comfort, safety, efficiency—the same **atmosphere** that has lent enchantment to these **larger** quality cars will be found to apply, point by point, to "The Little Aristocrat."

All is faithfully duplicated—all but the needless **size** and **power** and **price** which half a million prospective buyers have judged **unnecessary** as well as hopelessly **prohibitive.**

The Empire 25 is the utmost in roominess and comfort. It has **room** enough and **power** enough to carry five people anywhere. No hills can stop it. No car traveling 40 miles an hour can overtake it. No conditions are too difficult for it.

The success of the Empire in the hilly New England States has qualified it for service everywhere.

The Prize Design

No car outside of the $5000 class excels The Little Aristocrat in superb design.

This design is the result of a contest in which we offered a prize to the body designer whose specifications we accepted.

Nor did we stop with the mere **design.** We carried our big idea into the **finish** as elsewhere—finished the Little Aristocrat in Empire **Blue** and **Black Enamels,** the royal sign of **Quality.**

The upholstering we made **luxurious** and inviting. The seats we made **extra** wide and deep and the spring cushions **extra** thick and comfortable.

The doors also we made extra large, and with inside handles to facilitate getting in and out. Interior equipment throughout is only such as to please the most fastidious.

The dash and cowl we made of aluminum in one piece, thus following the custom of the **highest priced cars.**

The Steering Wheel we built extra large. It is 17 inches in diameter; most cars have 15 inch Steering Wheels.

The Steering Knuckles as well as the **axles** we made extra heavy for greater strength and safety.

The Clutch is disc type, Raybestos face, 9 inches in diameter instead of 5, the kind commonly used on cars of this size.

Big Hubs for style—big Artillery Wheels equipped with big tires for easy riding, tire-saving and maximum ground clearance—a free running board and fenders of the most approved type. Serve to put class and character into this car.

In short we give this car a distinction all its own. We built into it an appearance destined to attract, interest and gratify the great class of prospective buyers in the market for quality only. **And we succeeded!**

Details of the Perfect Mechanical Efficiency of the Empire 25:

Motor—25 H. P., 3½-inch bore, 4½-inch stroke—cylinders cast in pairs.

Cooling System—Large radiator in conjunction with a belt-driven fan. Circulation effected by the thermo-syphon method.

Valves — Fully enclosed, adjustable for wear.

Lubrication—Constant level, force feed.

Ignition—High tension magneto, set spark.

Clutch—Disc clutch, dry plate type, Raybestos faced.

Control — Single lever, center control. Throttle lever above steering wheel. Clutch, service and emergency brakes operated by foot pedals.

Steering—Full worm and gear type.

Brakes—Two external, contracting. Two internal, expanding on rear wheels.

Transmission—Three speeds forward and reverse, selective type, mounted on annular bearings. Unit power plant.

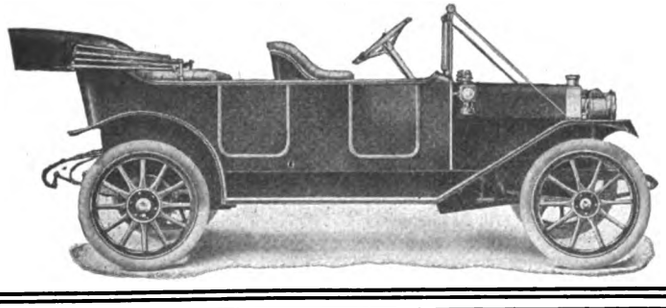
Gears—That are silent even when shifting.

Rear Axle—Semi-floating type.

Front Axle—I-beam section, drop forged. The size of the steeirng knuckles would do credit to a car twice the weight of the Empire.

Springs—Three-quarter elliptic rear, semi-elliptic front.

Wheels—Selected second growth, artillery type. 32-inch, quick detachable rims.



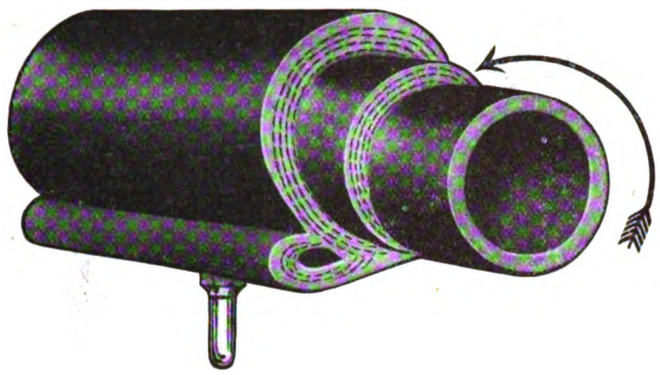
Wheel Base—104 inches.

Body—Aluminoid steel, wood trimmed; fore-door, full vestibule, straight lines from front to rear, ample room in tonneau, seats wide and deep, buffed leather cushions comfortably slanted, inside handles on doors.

Frame — Pressed steel, channel section, dropped, giving low center of gravity and easier riding qualities.

Gasoline Tank—Capacity, 12 gallons.

Standard Equipment — Includes magneto, gas lamps, side oil lamps, tail lamp, tools, repair kit, tire pump, jack and horn.



Mr. Dealer: This car should inspire **immediate action** on your part. There are people in every town, city and hamlet in the U. S. who will sit up and take notice of "The Little Aristocrat."

We have a wonderful proposition to make you. You should get it. You should also let us tell you even more about this splendid little car. Write us today.

"The Horn that's Made for the Discriminating"

TUTO HORN

THE TWO TONE HORN

No Rules Necessary

IT is not necessary to lay down any set of rules for the proper operation of the TUTO Horn, for its low and its loud notes are made to use in a logical way, just as you would speak in making a request or in the giving of a warning of imminent danger.

¶ There is no juggling required to get this "two-tone" effect, as is necessary when a bulb horn is supplemented by the one-note loud warning signal. A natural pressure on the TUTO button gives a low-abrupt-signal which is adequate for 90 per cent. of the warning. A full pressure on the same button instantly gets the loud-abrupt-note for emergencies or for use where the low note does not attract attention. From the low to the loud note, does not require any movement of hands or feet, as is necessary when going from the bulb to the button or to a foot pedal. This is made possible by placing the button on the steering wheel and right under the thumb.

¶ The TUTO horn is in a class by itself, as it actually works for your protection and is the only warning device which can be used effectively at short ranges and where every effort must be employed in the control of the car. The so-called long range warning signals of the one-loud note character, is very incomplete for modern motor car travel, as it is absolutely impossible to get a low abrupt signal of any effective duration from these warning devices and therefore they serve only as a supplement to the old inadequate bulb horn and add unnecessary duplication of accessories on the otherwise clean-cut car design of to-day.

¶ The TUTO horn operates in such a natural manner, that no thought or practice is required in the getting of an instant signal of any duration, either low or loud as occasion demands Therefore, it is the only warning signal which is completely adequate and best fitted for the standard equipment on modern motor cars.

This is the logical moment to think about next year's business.

Arrival of the Spring touring season multiplies responsibilities for tire dealers.

Thousands of cars which have been in winter retirement soon will be in service again. Your customers will want tires.

What tires are you going to sell them?

There are two important facts you should carefully consider in mapping out this season's campaign—the immediate requirements of your customers and the future of your business.

If you start right this Spring—establish your reputation for reliability—you not only satisfy your customers, but you lay the foundation for next year.

Once you satisfy a customer it is an easy matter to sell him again. Enough satisfied customers absolutely insure you a profitable business. Therefore, your permanent success as a tire dealer depends entirely upon the quality of the tires you sell.

United States Tubes

are made of the strongest, toughest rubber compound that can be produced by four tire makers working as a unit.

They are made of a rubber compound that will resist the deteriorating effect of age almost indefinitely.

They are absolutely uniform in quality and thickness.

Putting it concisely they are made by the United States four factory method.

Yet they cost no more than you are asked to pay for other kinds.

United States Tires have wearing qualities not possessed by other tires because they are made different from other tires.

They are the product of four great factories presided over by four groups of experts presenting an aggregate of tire-building knowledge not even approached by any other tire concern.

In United States Tires these experts have assembled the strongest individual points of four world-famous brands of tires.

Tires made as these tires are made offer you an absolutely certain foundation upon which to build up a big, lasting, profit-yielding business.

And they cost no more than other kinds.

The Atwater Kent Ignition System

Prepare For Summer

CONSIDER your ignition problem now.

Kick Switch Coil

Not when the old troubles have re-asserted themselves—not when you begin to have haunting suspicions of spark plugs, cables, coils, interrupters, carbureter and gasoline—not when you grudge the time it will take you to make the change and cling to the old unreliable system until you are thoroughly sick of the whole matter.

Change to an Atwater Kent System now before your car goes into service for the summer, and get the highest possible efficiency from your motor.

With it you can get better results than with the best dual system at less than half the cost. There is practically no wear, and its single simple adjustment seldom requires attention.

It is easily installed on cars of every make and model. In the entire system there are but three moving parts and one contact—no commutator, relay or vibrating coils are used. No more simple or efficient ignition device is made.

We are always glad to help you with your ignition problems. Write for new illustrated booklet "D" with full description and interesting ignition information.

Atwater Kent Mfg. Works:

Gentlemen—I have been using your Unisparker now more than two years and find that I can get from 2,000 to 3,000 miles out of a set of six dry cells and have never had any trouble with this system. It certainly has given me A-1 service, and is still in first-class shape. Very truly yours,

(S) Thomas Doran.

The Newtone

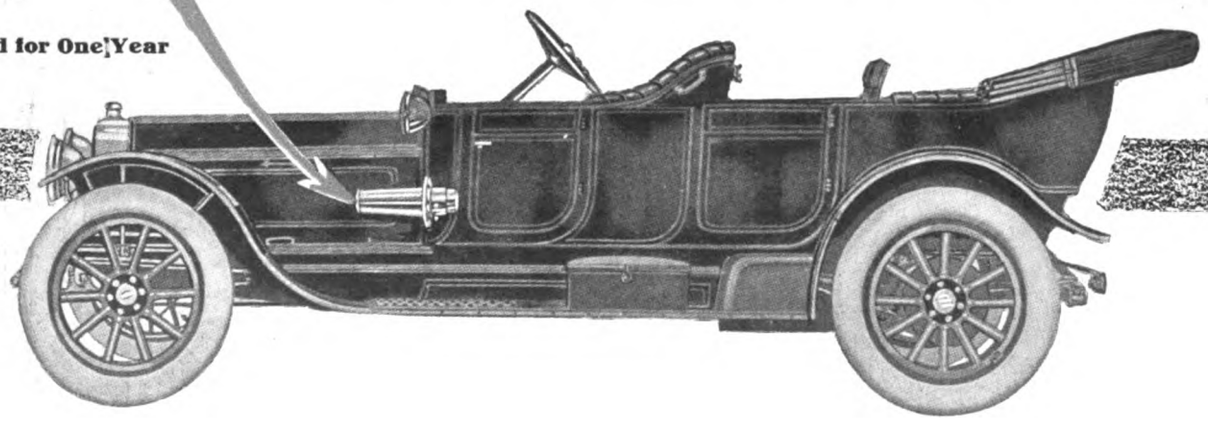
A touch of the button—

the warning note is spontaneous; powerful, clear, abrupt—a perfect danger signal. It's a powerful, melodious note, that never fails to warn, yet still retains an air of courtesy; that harsh, rasping sound, so obnoxious to the refined motorist, is entirely eliminated.

In crowded city traffic where instantaneous warning is vitally necessary, where there's no time to fumble for bulb or pedal—the **Newtone** renders perfect dependable service. In the country—on the winding road where a warning of approach far ahead is necessary, the **Newtone** is indispensable.

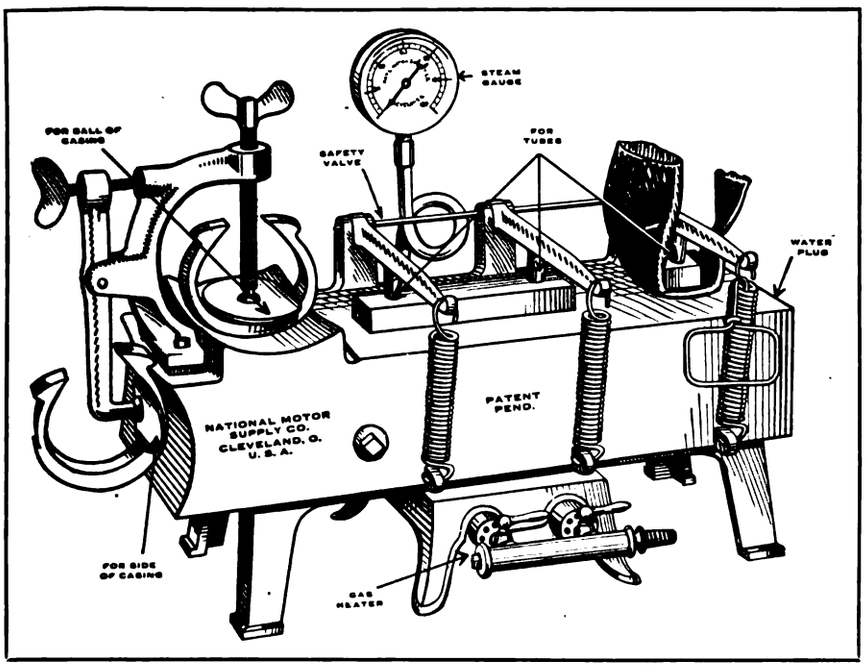
Nowadays It's the NEWTONE—"The Mile-Away Motor Horn"

The clear, powerful note it produces, the wonderful efficiency and economy of its tiny motor, the superior workmanship and facilities of a factory that makes over 80 per cent. of the automobile horns in America, has made the **Newtone** the most popular warning signal.



A little over a year ago the **Newtone** was first introduced to the public. Since that time thousands upon thousands have been sold; for the first six months even our unequalled facilities were inadequate to supply the demand.

The new electric motor which operates the **Newtone** is the real secert of its superior efficiency in warning and economy in operation. The fields of this new motor are made up of 75 very thin discs of special steel, thoroughly insulated. This new field construction produces more power, with practically 50 per cent. less current consumption of any other electric driven horn of this class.



The Chief Engineers of three leading American Automobile Manufacturers after a "Break-Down" Test stated that in their opinion the Newtone Motor Horn is the BEST warning signal made.

The Newtone Sells for $20.00 and is Guaranteed for One Year

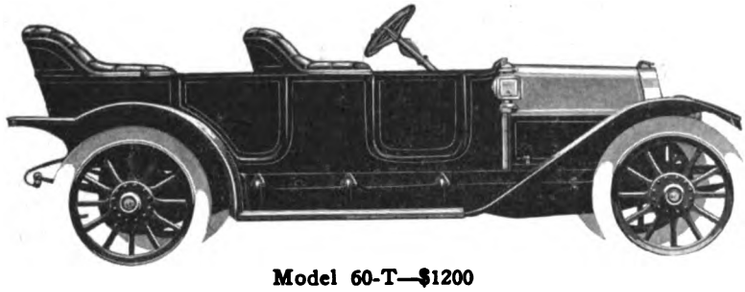
Overland



THE greatest difference in popular priced cars today is the difference in price. And this is entirely due to the size of the plants that produce them.

Our thirty-five horsepower touring car is priced at $1200. You seldom find a car of this size and type much below $1500 for the very simple reason that no other factory can produce it for this price. If they could they would. So why should you pay the difference?

Compare values and you will quickly realize the utter folly of paying $1500 for a car that can offer no more than our Model 60 at $1200.

Write for a catalogue. Please ask for book 1-44.

The Willys-Overland Company, Toledo, Ohio

Model 60-T—$1200

Wheel base, 111 inches; body, 5-passenger fore-door touring; motor, 4⅛ x 4½; horsepower, 35; Remy magneto; tires, 34 x 4 inch Q. D.; equipment, three oil lamps in black and brass finish, two gas lamps, horn and generator. Self-Starter, $20 extra.

THE MOTOR WORLD

Vol. XXXI New York, U. S. A., Thursday, April 4, 1912. No. 2

AMALGAMATION NOW IS ASSURED

Board of Trade Sure to Be Merged With N. A. A. M.—Velie "Forgets the Past" and Enrolls in N. A. A. M.

Although it now is absolutely certain that the Automobile Board of Trade will be merged with the National Association of Automobile Manufacturers, nothing further to that end was done at the regular meeting of the N. A. A. M. which occurred in New York yesterday, 3d inst., simply because nothing could be done.

The conference committees of the respective organizations — Messrs. Waldon, Bennett and Pope, representing the N. A. A. M., and Messrs. Hanch, Davis and Kittredge, representing the A. B. T.—have had several meetings, and were to have again conferred this week, but a number of things served to prevent and matters remain as they were.

Both organizations being corporations there are a number of legal knots to be untied before any amalgamation can be brought about, and the conference committees are engaged chiefly with the task of untying these knots and reconciling minor differences which, though small, may delay the actual amalgamation for two or three months, or possibly until early fall.

The changed and harmonious spirit of the times which is reflected by the pending merger of the two organizations was further exemplified by the election to membership in the N. A. A. M. at yesterday's meeting of the Velie Motor Vehicle Co., of Moline, Ill., in the person of L. M. Fuller, its secretary. Most of the members of the N. A. A. M. are members also of the Board of Trade, and it is only a little more than a year ago that the Velie company was at their throats with suits for $500,000 for damages due to alleged conspiracy growing out of the late and sometimes lamented Selden patent. The fact that the Velie people have forgotten and forgiven the past, therefore speaks for itself. Other than the addition of the Velie company to the roll, everything else done at the N. A. A. M. meeting was of a routine nature.

Gray & Davis Become a Corporation.

Gray & Davis, of Amesbury and Boston, Mass., the well-known makers of lamps and electric lighting systems, have converted their business into a corporation under the style Gray & Davis, Inc., their charter, which places the authorized capital at $1,250,000, being issued late last week. William Gray remains in control, and will fill the dual offices of president and treasurer. The other officials are: Alexander Churchward, vice-president; D. B. Kerr, secretary; D. Henry Elkins, assistant treasurer, and William B. Moses and William H. Gray, directors.

All of these gentlemen have been connected with Gray & Davis for several years. The only new men who have been brought into Gray & Davis affairs by the firm's transformation into a corporation are Turner & Tucker, the Boston bankers, who have sold in the open market $250,000 worth of the preferred stock of Gray & Davis, Inc.

Fisher Withdraws from Two Enterprises.

Carl G. Fisher, president of the Fisher-Gibson Co., of Indianapolis, Ind., one of the largest retail concerns in that State, has disposed of his interests and wholly retired from its affairs. The control has passed to Charles Sommers, of Indianapolis, who will succeed to the presidency; A. Waldheim, who becomes vice-president, and David May, of Cincinnati, secretary. Cecil E. Gibson, Fisher's old partner, will remain treasurer and general manager. The newcomers are the same men who joined with Gibson in the recent purchase and reorganization of the Empire Automobile Co. and who renewed the manufacture of the Empire car. Fisher, who is the big man in the Prest-O-Lite Co. and the Indianapolis Speedway, has withdrawn also from the movement to bring the embryo Edwards Motor Car Co. to Indianapolis, for which purpose Toledo parties are conferring with Messrs. Edwards and Stoddard in New York.

TIRE PRICES AGAIN INCLINE UPWARD

Belief That More or Less General Revision is at Hand—But Only One Maker's Figures Are Known.

Reports that an increase in the price of tires is impending have been flying thick and fast during the past two days and, despite several denials, the belief prevails that a more or less general revision of the prevailing figures will come to pass.

To date, however, the Fisk Rubber Co. is the only manufacturer that is positively known to have decided to raise prices; and in that instance the increase is general only so far as it relates to inner tubes and affects only trade prices and not the catalog listings. The only casings affected are those up to 3 inches, which will be advanced 10 per cent. on April 10th. On the same day, the price of Fisk-Dunlop tubes will be raised 15 per cent. and all other tubes 10 per cent. As 3-inch casings are only used on the lighter cars, particularly on the Ford, no very considerable number of car manufacturers will be affected.

At the New York offices of the United States Tire Co., Diamond Rubber Co. and B. F. Goodrich Co., it is positively denied that an advance in tire prices is contemplated.

Two Suits for Windshield Infringement.

Charging infringement of its patent No. 1,011,892, issued to one Martin L. Williams on December 12, 1911, and covering an improvement in windshields for automobiles, the Twentieth Century Motor Car & Supply Co., of South Bend, Ind., last week filed suits in the New York and Connecticut districts of the Federal courts. The suit which was begun in the United States District Court for the Southern District of New York is directed against the Ideal Windshield Co., Inc., of 1926 Broadway, New York City, while the Connecticut action names the Holcomb Co., of New Haven, as defendant.

Digitized by Google

GOODRICH'S NEW CAPITALIZATION

How the $45,000,000 Will Be Apportioned Under New Charter—Sales of "Melon" Restricted for Six Months.

Having been ratified by the stockholders, and the "melon" having been made ready for cutting, the legal details necessary to consummate the transfer of the B. F. Goodrich Co. from Akron, Ohio, whose capital is $20,000,000, to the new company of the same name, capitalized at $45,000,000 under the laws of New York, are now well in hand. The transfer will be as of April 1st and conveys the entire Goodrich property, assets, business and good will, to the new company, excepting only certain sums which, according to agreement, are to be retained by the Ohio corporation to pay dividends and other obligations. The controlling interest in the latter company, however, will retain control of the new company and the present management will remain unchanged.

Among other things, the charter of the New York company will provide that until the holders of two-thirds in interest of each class of stock shall otherwise direct, the new company shall pay such taxes in the State of Ohio as may be required to render its stock exempt from taxation in that State.

The capital of the new corporation, as already has been stated in the Motor World, will be divided into 450,000 shares of $100 each, of which 150,000 shares will be 7 per cent. cumulative preferred stock, and 300,000 common stock. At least 3 per cent. of the preferred stock will be retired each year after July 1, 1913, from the net surplus profits of the new company. Dividends may be paid on the common stock, but none of the stock of the new company received by the Goodrich company of Ohio or its stockholders shall be sold, distributed or otherwise disposed of during the sixmonth period from the time of delivery of the stock to the bankers, except with the consent of the latter.

These bankers, Goldman, Sachs & Co. and Lehman Bros., of New York, and Kleinwort, Sons & Co., of London, have acquired 78,000 shares of the new preferred stock and 30,000 shares of the new common stock—par value, $10,800,000—paying therefor $7,800,000, and receiving also an amount equal to the accrued dividends from April 1, 1912, on these 78,000 shares of preferred. The bankers have agreed also to purchase all or such part of an additional 66,667 shares of the new company, at $67.50 per share, as the present Goodrich company may elect to sell. The three stockholders who were parties to the agreement have reserved on behalf of all holders of the present common stock desiring to join therein, the right to purchase from the bankers all or any part of 28,000 shares of the new preferred stock at par value and accrued dividends thereon from April 1, 1912.

The transfer of the corporate existence of the Goodrich company from Ohio to New York entails, as the entire trade knows, the cutting of one of the most uncommonly luscious "melons" which recently has ripened in the industrial field. The holders of preferred stock in the old company are given the option of $120 per share in cash or 1.2 shares of the new preferred issue, while the holders of the old common stock will receive 2.7 shares of the common stock and $78 in cash for each share of the present common stock which they may hold.

Simms Property Basis for Two Dickers.

Although it is known that a representative of the Bosch Magneto Co. has inspected the plant of the Simms Magneto Co., at Bloomfield, N. J., with a view of purchasing all or some part of it, reports that the purchase had been effected are authoritatively denied by Manager Stiefel, of the Simms company. He admits that negotiations of some sort were in progress but absolutely refuses to say what is their nature. The Bosch people also assume the same attitude. According to other reports, the Eisemann Magneto Co. also is dickering for either the Simms factory building or machinery, but Manager Leblanc, of the Eisemann company, denies that such is the case, which denial, however, caused an expression of explosive surprise when it was repeated to other interested parties. The Simms plant in Bloomfield was not completed until late last year and really never has been in full operation, one obstacle after another having served to delay its productiveness. The factory has been at practically a complete standstill for several months and the future of the company a matter for speculation, which, however, shortly will be settled.

To Make Sheet Metal Parts in Indianapolis.

Sheet metal parts, guards, hoods, tanks, underpans, running boards, tool boxes, etc., are to be manufactured by the Scheidel-Thompson Mfg. Co., which just has been organized in Indianapolis, and which has leased quarters in the Industrial Building in that city. Actual operations, however, will not begin until about June 1st. The officers of the company, which is capitalized at $50,000, are George I. Scheillig, president; Bert E. Thompson, vice-president and general manager; R. F. Scheidel, secretary and treasurer, and George H. Scott, superintendent. Thompson formerly was factory manager for the Hayes Mfg. Co., of Detroit, and Scheidel and Scott, superintendent and assistant superintendent, respectively, of the same company. Messrs. Hayes and Emmons, of the Hayes company, were in Indianapolis a few days since, visiting Thompson, but it is stated that there is no Hayes money whatsoever in the Indianapolis enterprise.

OVERLAND RECOVERS TRADE MARK

Former Canadian Agent Who Pre-empted It is Put to Rout—His Overland Company Also Evaporates.

George R. Rastall, who, having pre-empted the Overland trade mark in Canada, induced himself to believe that he was the Overland Automobile Co. of Canada, Ltd., has discovered that he is something else; and meanwhile the Willys-Overland Co., of Toledo, Ohio, has recovered the right to use its trade mark in the Dominion, and Rastall, it is understood, has left that country.

When, in January last, John N. Willys became cognizant of the state of affairs created by Rastall, who at one time was the Overland agent in Regina, Sask., he at once took vigorous action, as was then reported in the Motor World. He instituted suit in the Exchequer Court asking for damages, and the immediate result was that Rastall and his partner changed the name of their company to the Canadian Motors and surrendered to the government the trade mark "Overland," which finally was issued to the Willys-Overland Co. last week.

Meanwhile Rastall had been arrested on a charge of embezzling the funds of his company and his present whereabouts are unknown. The suit for damages, accordingly, will not be pressed, and as one of Rastall's former partners, F. R Mahoney, has the Overland agency in Regina and is doing a good business, he will be left unembarrassed.

When Rastall incorporated the Overland Automobile Co. of Canada, Ltd., he declared that it was in pursuance of an agreement entered into between himself and Willys, and for the purpose of assembling Overland cars in Canada. He alleged that Willys had agreed to take one-half of the $500,000 capital stock of the company, which, he added, "is fully organized and doing business and is controlled absolutely by myself," and having quietly registered the trade mark "Overland" he stated his purpose to commence the manufacture of Overland cars in Canada in the very near future.

Willys denied every statement made by Rastall and legal action followed his denial, with the result that Rastall soon was discomfited and placed in an embarrassing position. The legal proceedings resulted, as stated, in the evaporation of the Overland Automobile Co. of Canada, Ltd., and the recovery by Willys of his right to the trade mark "Overland."

To Make Motor Trucks in Maine.

The Wade & Dutton Motor Car Co., of Lewiston, Me., is about to engage in the manufacture of trucks in that city. For the purpose it has secured manufacturing facilities on Park street.

FEBRUARY EXPORTS ARE DOUBLED

Month's Total, $2,620,454, Established a New High Mark—Great Gains Made in All Save Two Countries.

January's new high record in the exportation of American-made automobiles and parts—$2,427,891—was surpassed by the second month of this year, when a total of $2,620,454 worth of cars and parts was shipped abroad, as against $1,289,888 worth exported in the same month of 1911, representing a gain of $1,330,566, or 105 per cent. Of this total sum, $2,274,489 was the declared value of 2,403 cars, as compared with 1,023 cars, valued at $1,075,670, sent abroad in the corresponding month of 1911. The remainder, $345,965, of course, represented the value of parts, as against $214,218 in the same month of the preceding year. The average value of the exported cars, however, dropped from $1,051 in February, 1911, to $946 in February, 1912.

Were it not for the small losses registered by Germany and Italy, aggregating less than $9,000, the February figures would have the unique distinction of showing gains in every one of the twelve geagrophical divisions enumerated in the government statistics. Even France and the West Indies, which for several months had shown decreasing purchases, disclose decided gains, taking $39,221 and $42,433 worth of cars alone, as compared with $28,242 and $40,793 worth of cars and parts together, respectively. Canada, by increasing its purchases from $670,090 to $774,270, again attained the lead which it had lost in January, 1912. Great Britain, in second place, took $534,398 worth of cars alone, as against $150,142 worth of cars and parts in February, 1911—a gain of fully 260 per cent. British Oceania, also, showed heavy gains, its purchases amounting to $334,831 in February last, as against $101,728 in the same month of 1911—an increase of 219 per cent.

The figures for the eight months ending February, 1912, reflect the extraordinary gains made in the first two months of this year, no less than 12,347 complete cars having been shipped abroad, as compared with 5,840 cars in the same period of the preceding year, showing a gain of 111 per cent. in the number of cars and 75 per cent. in their value. Parts valued at $2,426,264 were shipped, bringing the total of cars and parts to $14,490,647—a gain of over $6,000,000 over the $8,198,234 in the corresponding period of the preceding year. The table in detail is shown below.

Big Gains in Gas Engine Exports.

According to the government export statistics for the month of February, no less than 954 complete gasolene automobile motors were shipped abroad, valued at $113,871. During the eight months ending February, 1912, 3,484 complete motors, valued at $417,318, were sold to other countries, the figures showing that more than one-fourth of the total for the eight months' period were shipped in the last month, indicating a rapid increase in this trade. No comparative figures for previous years are available, as the statistics did not include motors separately until July, 1911.

Tire Exports Continue to Increase.

During the month of February, 1912, the exportation of American tires again increased substantially, attaining a total value of $267,036, as compared with $179,047 in the same month of 1911, a gain of more than 45 per cent. During the eight months ending February, 1912, $1,641,373 worth of tires were shipped abroad, as against $1,194,720 worth in the same period of the preceding year, an increase of almost 37 per cent.

Michigan Men Distributing Their Stock.

The 21 citizens of Grand Rapids, Mich., who subscribed $5,000 each to induce the Decatur Motor Car Co. to remove from Decatur, Ind., to Grand Rapids, Mich., where the business was reorganized under the title Grand Rapids Motor Truck Co., have formed an underwriting syndicate and now are offering the shares of the truck company to the public. They are giving one share of common stock with each purchase of preferred, which latter is of $100 par value.

STUDEBAKER IN ANNUAL SESSION

Big Corporation Re-elects Officers and Discloses Its Financial Condition—Profits, $2,691,000; Surplus, $944,832.

Practically no change was made in the official make-up of the Studebaker Corporation of South Bend, Ind., and Detroit, Mich., at its annual meeting, which occurred at its legal office in Jersey City, N. J., on Monday last, 1st inst. Philip Lehman, of Lehman Bros., bankers, succeeded Paul Sachs, of Goldman, Sachs & Co., as a director, and James Newton Gunn replaced F. K. Parks, who found it advisable to resign in January last, and the directors in turn re-elected all of the former officers save Parks, who had served as one of the several vice-presidents; he was succeeded by George M. Studebaker. Walter E. Flanders was among those retained in office, the full slate of officials being as follows: J. M. Studebaker, chairman of the board; Frederick S. Fish, president; Clement Studebaker, Jr., first vice-president; George M. Studebaker, vice-president; Walter E. Flanders. vice-president; A. R. Erskine, treasurer; Scott Brown, secretary and general counsel; James Newton Gunn, general manager.

Directors—Frederick P. Delafield, Frederick S. Fish, Walter E. Flanders, Henry Goldman, James Newton Gunn, A. Barton Hepburn, William R. Innis, Philip Lehman, Clement Studebaker, Jr., George M. Studebaker, J. M. Studebaker, John R. Turner.

The annual report of the company was rendered by Clement Studebaker, Jr., first vice-president. The financial statement for the year ended December 31st, which accompanied it, showed profits amounting to $2,691,847.94, which, after paying dividends of $708,750 and charging off extraordinary expenses of $396,478.99, left a surplus of $944,832.04.

According to Vice-President Studebaker, the results in volume of sales and profits from the automobile division of the corporation are much larger than ever before.

and sale of electric vehicles and the higher priced gasolene cars and two-speed medium priced cars, and restricting production to the two popular priced cars which now are being marketed, and the resultant liquidation of the departments concerned, "proved to be unexpectedly costly," to quote Mr. Studebaker. "But the move," he added, "was a wise one and the results will be apparent in the future." He also stated that in view of the large trading profits for the year it was deemed advisable that large sums immediately be written off and a satisfactory reserve created against these and other exceptional expenses and losses.

The Studebaker output of automobiles for the year 1912 will be by far the largest in the company's history, and Mr. Studebaker states that it is expected that the entire production will be marketed without trouble.

The financial condition of the corporation is shown in detail by the accompanying tables, which, of course, do not take account of the recent note issue of $8,000,000 which was created since December 31st and therefore does not enter the financial affairs of the corporation for the fiscal year 1911.

R. P. Henderson Defers His Statement.

R. P. Henderson, who is to become president of the Henderson Motor Car Co., of Indianapolis, when it is organized, and which will make a popular price car bearing his name, did not issue the official statement which was promised for Friday last and which it was expected would shed more light on the new enterprise in which he is to engage. He now states that it will be a month or more before he will be in position to make a definite statement. On Friday, however, Charles P. Henderson, president and general manager of the Henderson Motor Sales Co. gave out a statement confirming the reports concerning the Henderson-Cole affairs which were published in last week's Motor World. It emphasizes that when the Henderson Motor Sales Co. goes out of existence on July 1st next, R. P. Henderson will be practically the only member of its working organization who will not join the Cole Motor Car Co., which will practically absorb the Henderson Motor Sales Co., and thereafter will not merely manufacture its own cars, but actually market them.

Jeffery-DeWitt Takes Visible Plug.

The Jeffery-DeWitt Co., of Detroit, has acquired the patents, trade mark and all other rights and title to the visible spark plug heretofore marketed by the Visible Spark Plug Co., of that city. The plug hereafter will be included in the better known productions of the Jeffery-DeWitt line. The distinctive feature of the visible plug, from which it takes its name, is an opening on either side through which the spark can be seen, thereby rendering it possible to observe the sparking of the plug without removing it from the engine.

STUDEBAKER CORPORATION'S ANNUAL FINANCIAL STATEMENT

THE WEEK'S INCORPORATIONS

Detroit, Mich.—Triplex Tire Co., under Michigan laws, with $150,000 capital; to manufacture automobile tires.

Loudsborg, Kan.—Great Eagle Motor Devices Co., under Kansas laws, with $130,000 capital; to manufacture automobile appliances.

Chattanooga, Tenn.—Citizens Automobile Co., under Tennessee laws, with $15,000 capital; to deal in automobiles and accessories.

Beaver Dam, Wis.—Beaver Dam Automobile Co., under Wisconsin laws; to deal in automobiles. Corporators—J. G. Beck, Alvin Beck, Rudolph Beck.

Portland, Me.—C. A. Scott Co., under Maine laws, with $10,000 capital; to deal in automobiles. Corporators—Hugh Lawless, Charles A. Scott and others.

Los Angeles, Cal.—Automobile Flagman Co., under California laws, with $100,000 capital. Corporators—E. C. Reynolds, H. E. King, H. F. Webster and others.

Council Bluffs, Iowa—Twin City Auto Co., under Iowa laws, with $25,000 capital; to deal in automobiles. Corporators—S. V. Bernhart, J. J. Kline,, M. C. Goodwin.

Chicago, Ill.—Downtown Garage Co., under Illinois laws, with $4,000 capital; to operate a garage. Corporators—J. Carlton Abbott, Ralph W. Olmstead, W. B. Atkins.

Augusta, Me.—Omaha Motor Co., under Maine laws, with $1,000,000 capital; to manufacture and deal in motors. Corporators—R. S. Buzzell, E. J. Pike and others.

Boston, Mass.—Picardie Woven Fabric Co., under Massachusetts laws, with $100,000 capital. Corporators—Merrill Griswold, Henry Endicott, Jr., Robert J. Richardson.

Boston, Mass.—Chauffeurs' Legal Association, under Massachusetts laws, with $10,000 capital. Corporators—Jay R. Benton, George A. Kearsley. Francis D. Harrigan.

Jersey City, N. J.—Atlantic Vehicle Co., under New Jersey laws, with $340,000 capital; to deal in all kinds of vehicles. Corporators—M. Black, L. R. Jillson, J. R. Turner.

Boston, Mass.—Williams Auto Co., under Massachusetts laws, with $2,500 capital; to deal in automobiles. Corporators—William T. Hanley, James F. Hanley, Frederick W. Ryan.

Indianapolis, Ind.—J. I. Case Co., under Indiana laws, with $5,000 capital; to deal in motor tractors, etc. Corporators—J. I. Case, R. J. Case, H. M. Walter, all of Racine, Wis.

Boston, Mass.—Auto Sales Co., under Massachusetts laws, with $25,000 capital; to deal in automobiles. Corporators—Leroy P. Russell, Eugene J. Courtney, Louis H. Melzan.

Evansville, Ind.—Victor Automobile Co., under Indiana laws, with $8,000 capital; to deal in automobiles. Corporators—P. B. Fellwock, W. E. Fellwock, J. F. Fellwock, H. F. Nolte.

Eau Claire, Wis.—Eau Claire Vulcanizing Co., under Wisconsin laws, with $2,000 capital; to do a general tire repair business. Corporators—F. E. Hall, E. L. Moffett, B. F. Headley.

East Orange, N. J.—Aymar & Bradley Co., under New Jersey laws, with $50,000 capital; to deal in motor cars, etc. Corporators—H. H. Picking, C. O. Geyer, F. E. Ruggles.

Boston, Mass.—Alpena Boston Co., under Massachusetts laws, with $10,000 capital; to deal in motor cars. Corporators—Charles C. B. Merrill, Claron A. Cook, Peter Begory.

San Diego, Cal.—Auto Service Co., under California laws, with $50,000 capital; to operate a general automobile business. Corporators—E. B. Harvey, W. U. Smith, A. J. Morganstern.

Chicago, Ill.—Economy Garage Co., under Illinois laws, with $2,500 capital; to operate a garage and deal in motor cars. Corporators—John C. Eastman, Lester L. Jones, W. Frank Dunn.

Boston, Mass.—Tank o' Gas Co., under Massachusetts laws, with $200,000 capital. Corporators—Lewis H. Josselyn, Edward S. Everett, Charles E. Osgood, George H. Davis, Theodore M. Josselyn.

Edgewater, N. J.—Steinbock Engineering Co., under New Jersey laws, with $1,000,000 capital; to manufacture automobiles. Corporators—E. J. Forhan, F. B. Knowlton, J. McLaren, all of New York City.

Newark, N. J.—North Jersey Auto Supply Co., under New Jersey laws, with $80,000 capital; to conduct a general automobile business. Corporators—M. Permission, C. G. Butler, E. C. Mehroff, F. W. Mead.

Brockton, Mass.—Kelley-Damon Auto Supply Co., under Massachusetts laws, with $25,000 capital; to deal in motor cars and supplies. Corporators—George E. Damon, Stephen H. Kelley, George F. Damon.

Chicago, Ill.—Chicago Electric Motor Car Co.. under Illinois laws, with $110,000 capital, to manufacture automobiles and accessories. Corporators—David F. Rosenthal, Leo S. Kositchek, J. L. Cossman.

Worcester, Mass.—Worcester Auto Parts Co., under Massachusetts laws, with $10,000 capital; to manufacture automobile parts and sundries. Corporators—James N. Heald, Cyrus N. Cowan, John A. Doane.

New York, N. Y.—Foster Appliances and Specialties Co., under New York laws, with $30,000 capital; to manufacture patented articles. Corporators—E. F. Wood, W. J. Foster, J. A. Hodge, all of New York City.

New York, N. Y.—Havers-Imperial Auto Sales Co., under New York laws, with $25,000 capital; to deal in motor cars. Corporators—Milton Mayer, James McBrien and John F. Barrett, all of 52 William street.

Brooklyn, N. Y.—Ocean Hill Garage, Inc., with $1,000 capital; to operate a public garage. Corporators—Harold Umansky, 151 Christopher avenue; Samuel Umansky and Joseph Umansky, both of 26 Thatford avenue.

Hammond, Ind.—Frederick L. Heintz, Inc., under Indiana laws, with $100,000 capital; to manufacture automobile tires, etc. Corporators—L. M. Heintz, F. L. Heintz, J. G. Vanderveer, Louis Connaghan, Conrad Fischer.

San Francisco, Cal.—Pacific Motor Fire Apparatus and Supply Co., under California laws, with $25,000 capital; to deal in motor fire apparatus. Corporators—H. L. Hudson, C. L. Daggett, Wm. F. McKannay and others.

New York, N. Y.—Washington Square Taxicab Co., under New York laws, with $5,000 capital; to operate taxicabs. Corporators—Lorenzo A. Cuneo, William E. Podesta and Frederick Cuneo, all of 12 East Eighth street.

Buffalo, N. W.—Buffalo Electric Vehicle Co., under New York laws, with $1,000,000 capital; to manufacture electric vehicles. Corporators—William J. P. Seipp, William C. Feuchter and Thomas R. Wheeler, all of Buffalo.

New York, N. Y.—Mayer Auto Specialties Co., under New York laws, with $15,000 capital; to deal in automobile supplies. Corporators—Simon G. Mayer, Albert L. Kull, both of 1731 Broadway, and James McBrien, 52 William street.

New York, N. Y.—Parker J. Manning Auto Co., Inc., under New York laws, with $500 capital; to deal in automobiles. Corporators—Parker J. Manning and Ellen E. Manning, both of 447 East 135th street, and Isaac Levison, 309 Broadway.

New York, N. Y.—Detroiter Company of New York, under New York laws, with $5,000 capital; to deal in motor cars. Corporators—Herbert G. Outwater, 425 West 160th street; Andrew Walz and Jacob Walz, both of 504 West 111th street.

New York, N. Y.—Standard Auto Rent-

Digitized by Google

ing Co., under New York laws, with $10,000 capital; to rent automobiles. Corporators—David C. Goodman, 157 East 73d street; William Machol, 11 Broadway; Edwin B. Koenig, 1190 Madison avenue.

New York, N. Y.—Market Auto Garage Co., under New York laws, with $1,000 capital; to operate a public garage. Corporators—Patrizio Garofalo, 2161 First avenue; John Sivigila, East 108th street; James M. Vincent, 145 East 11th street.

Cincinnati, Ohio—Price Hill Auto and Garage Co., under Ohio laws, with $1,000 capital; to deal in automobiles and supplies and operate a garage. Corporators—John Radel, Michael Wolfer, Stephen Radel, William J. Wirmel and John F. Ruehlman.

New York, N. Y.—Auto Mechanical Devices Co., under New York laws, with $10,00 capital; to manufacture all kinds of automobile devices. Corporators—Louis H. Smith, John Sommor, both of 55 John street, and Henry G. Ingersoll, 13 Park Row.

Grand Rapids, Mich.—Commercial Service Truck Co., under Michigan laws, yith $175,000 capital; to manufacture commercial motor vehicles. Corporators—Phillip Moran, J. W. Landeann, G. H. Greenbauer, Sybrant Wesselius, Henry Brink and J. H. Hagen.

New York, N. Y.—O. E. Short & Co., under New York laws, with $25,000 capital; to manufacture and deal in motors, motor cars, etc. Corporators—Orville H. Short, 15 West 91st street; Harlan W. Short, Morsemere, N. J.; H. L. Starr, 1208 Clay avenue.

Amesbury, Mass.—Gray & Davis, Inc., under Massachusetts laws, with $1,250,000 capital; to manufacture automobile accessories, etc. Corporators—William Gray, Alexander Churchward, David B. Kerr, William B. Moses, D. Henry Elkins, William H. Gray.

Springfield, Mass.—Springfield Crude Oil Engine Co., under Massachusetts laws, with $500,000 capital; to manufacture internal combustion motors. Corporators—William F. Miller, Howard R. Bemus, Silas L. Kenyon, Samuel D. Sherwood, Leon J. Hurley, Harry C. Ellis.

Augusta, Me.—Jackson Petroleum Motor Co., under Maine laws, with $500,00 capital; to manufacture internal combustion motors. Corporators—Joseph Williamson, Ernest L. McLean, M. D. Yeaton, Samuel Titcomb, R. S. Buzzell, E. J. Pike, W. E. Dudley, E. A. Hussey and others.

New York, N. Y.—Standard Resilient Wheel Co., under New York laws, with $500,000 capital; to manufacture a patent automobile wheel. Corporators—Joseph Gaynor, 551 Fourth avenue; Philip B. Verplanck, 2122 Fifth street, and Solomon Jochelson, 457 Grand street, New York.

Increases of Capital Stock.

Detroit, Mich.—Invincible Starter Co., to $25,000.

Changes Among Prominent Tradesmen.

Fred L. Morgan, formerly with the Baker Motor Vehicle Co., of Cleveland, Ohio, has joined the staff of the Standard Electric Car Co., of Jackson, Mich. He will act as a special representative.

M. O. Crawford, formerly manager of the advertising and service department of the Colby Motor Co., Mason City, Iowa, has become connected with the Zenith Carburetter Co., of Detroit.

A. M. Laycock, former chief engineer for the A. O. Smith Co., of Milwaukee, has been appointed chief engineer of the automobile axle department of the Sheldon Axle Co., of Wilkes-Barre, Pa. Before joining the Smith company Laycock had been employed in the engineering departments of the English Dailmler company.

Charles Measure, former manager of the Goodyear branch in New York, has been appointed manager of the motor truck tire department of the Federal Rubber Mfg. Co., of Milwaukee. Measure, who is one of the veterans of the tire trade, was identified with Morgan & Wright for 11 years before joining the Goodyear staff in 1906.

Floyd A. Allen, assistant general manager of the Buick Motor Co., Flint, Mich., has been appointed treasurer of the Michigan Motor Castings Co., of that city, both companies being General Motors' possessions. The appointment does not alter Allen's relations with the Buick company, as it is merely in the line of adding to his duties.

In order to facilitate the work, L. A. McKay, who served as Western sales manager for the Franklin Automobile Co., with offices in the factory at Syracuse, N. Y., has been transferred to Minneapolis, Minn., where he has established headquarters. He will handle the Franklin business in nine of the surrounding States, and also in the Canadian provinces of Manitoba and Saskatchewan.

O. R. Hardwell, formerly with the Charles H. Fuller advertising agency, has been appointed advertising manager for the Paige-Detroit Motor Car Co., of Detroit. Hardwell has had experience in the automobile field, having once served as advertising manager of the Canada Cycle and Motor Co., maker of the Russell car, the first in America to employ a Knight sleeve-valve engine.

L. E. Bissell has been appointed manager for the F. B. Stearns Co.'s Atlanta (Ga.) branch to fill the vacancy caused by the transfer of John F. Toole to the management of the Stearns company's Pacific Coast branch in San Francisco. Bissell is well acquainted with the Southern territory, having represented the Peerless Motor Car Co. for several years in that part of the country.

F. E. Howell, special representative of the Diamond Rubber Co.'s truck tire department, has resigned that post to become district manager of the Chase Motor Truck Co., of Syracuse. He will make his headquarters in Philadelphia. Ray Lindsley, heretofore identified with the Denniston truck interests in Buffalo, also has joined the Chase staff and will be associated with the Chase branch in Buffalo.

J. C. Slager, sales manager for the Apple Electric Co., Dayton, Ohio, has been promoted to the post of assistant manager. His elevation has resulted in the calling of F. G. W. Sudrow from the management of the Apple branch in Detroit to the sales management at headquarters, while the vacancy in Detroit has been filled by the appointment of H. J. Shire, formerly with the Roller-Smith Co. The branch also has been removed from 1005 Woodward avenue to 1310 Majestic building.

Woman Heads the New Van Company.

The Van Motor Car Co., which was formed about two years ago in Grand Haven, Mich., to build a low-priced runabout but which got into difficulties before it built very many of them, has been purchased by H. M. Pierce, J. A. Owen and Mrs. L. M. Strong, of Grand Rapids, Mich., who are the owners of the Wealthy Heights Garage, in that city. Mrs. Strong is president of the new company and thereby takes rank as the first woman to occupy such a position in the automobile industry. Pierce is vice-president and Owen is secretary and treasurer. The company purposes to continue the manufacture of what was the Van runabout but which hereafter will be called the Pioneer roadster, and which will list at $750.

Motor Trucks Agitating the Davenporters.

The East Davenport Machine Shop, of Davenport, Iowa, has embarked in the manufacture of motor trucks. Two trial vehicles are now in course of construction and the extent of future production depends somewhat on the result of the work which they perform. Apart from this enterprise the Davenport Commercial Club is engaged in an effort to form a truck company in that city. A Chicago man is spurring on the club with assurances that he can obtain $65,000 or $70,000 for the venture.

Cole to Locate Branch in Detroit.

The Cole Motor Car Co., of Indianapolis, has executed a lease for the building now in course of erection at the corner of Willis and Woodward avenues, in Detroit, which will be maintained as a Cole branch in that city. The building will be 40x75 feet, and will have large show windows on both avenues.

Gets Great Slice of Motz Territory.

The Standard Tire and Rubber Co., 104-106 Portland street, Boston, Mass, has acquired the Motz tire agency for all of the New England States. The Standard company already is well established and thoroughly familiar with its territory.

August Gruss has purchased the garage of John Becker in Scotland, S. D.

Peter & Son are building a garage and repair shop in Long Prairie, Minn.

Milford, N. H., now boasts of another garage. Edward J. Hopkins just has opened it.

Orval McDonald has leased the Proehl building in Mapleton, Minn., and opened a garage therein.

Klemish & Dickelman is the style of a new firm which has opened a garage at Kewaunee, Wis.

Oscar Wagner is preparing to build a 341 Trumbull street, Hartford, Conn. He has the agency for Oakland cars.

The Kokomo Auto and Machine Co., Cole agent at Kokomo, Ind., has changed its name to C. F. Seaward & Son.

Alan Roxborough and William F. Sanderson have formed a partnership and opened a repair shop and garage at 2120 West Pico street, Los Angeles, Cal.

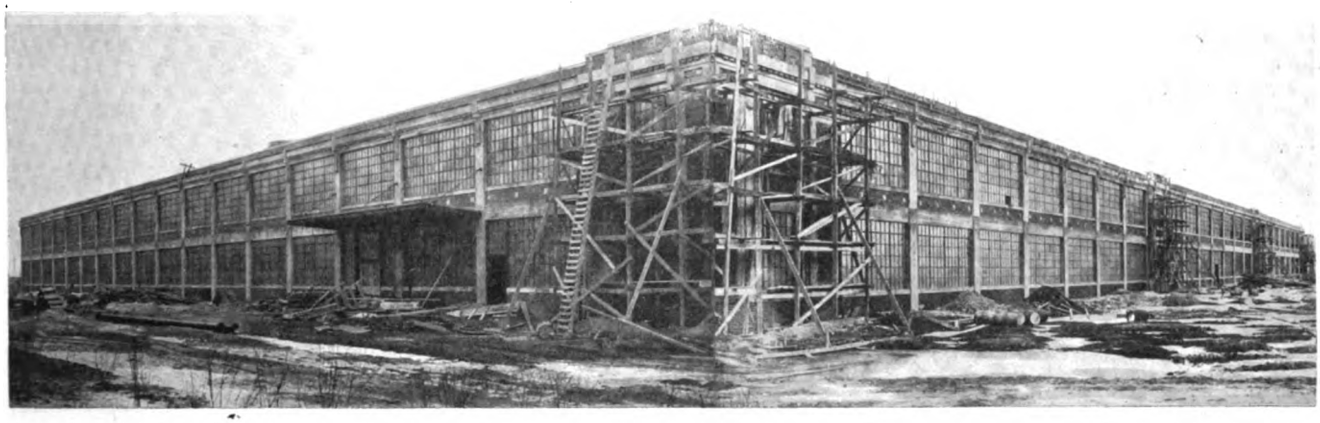
L. C. Buxton, one of the veterans of the Pacific Coast trade, has opened a salesroom at 1226 South Olive street, Los Angeles, Cal., where he will show Moon cars.

Saunders & Cole, who conducted a garage in Bryan, Tex., under the style Imperial Garage, have dissolved partnership. Saunders will continue the business alone.

Holmes & Howe is the style of a new firm which has been organized to handle the Stearns-Knight car in Kansas City, Kan. Its salesrooms are at 3330 Main street.

Arthur Foraker and Victor N. Cushman have formed the Potomac Motor Car Co. and established salesrooms at 1218 Connecticut avenue, Washington, D. C. They will handle Marmon cars.

The name of the Day-Rice Automobile Co., New Orleans, La., has been changed to Day Autumobile Co., Rice having retired from the company. His entire interest was purchased by Mrs. B. H. Day.



Elwin S. Carll and M. G. Morse, of Waterboro, Maine, have bought the business of the Ford Auto Co., on Mechanic street, Sanford, Maine. They will continue to operate it under the old style.

Bert J. Werber is preparing to open a salesroom and service station at 1109 Pine street, St. Louis, Mo. He has the agency for Poss trucks, and will do business under the style Poss Motor Truck Agency.

The Imperial Automobile Co. has been formed in Cleveland, Ohio, with headquarters at 2025 Euclid avenue, to handle the Imperial line of cars. M. M. Eiseman and Edward McCart constitute the company.

The Des Moines Rambler Co. has been organized by Earl H. Scrippe and J. Givin garage and repair shop on Pearl street,

MAMMOTH PLANT IN WHICH CONTINENTAL MOTORS WILL BE MADE IN DETROIT

The picture shows only one corner of the immense building; several other structures are behind it. Factory covers 12 acres and contains 240,000 square feet of floor space. Annual capacity, 18,000 to 20,000 motors.

William E. McNaught and Oscar Rosenwinkel are preparing to establish a garage in Norwood, Mass.

H. Rea Selby has opened salesrooms in Portsmouth, Ohio. He will handle the American line of cars.

M. C. Tork and H. W. Waddington have purchased the garage formerly operated by Evans & Detens, Highlands, Cal.

J. B. Baldy, Jr., has organized the United Motor Co. in Tacoma, Wash. He will handle Stevens-Duryea, Maxwell, Brush and Cole cars.

Lane Beard has opened a garage in the Belville building, on Center street, Augusta, Ill. He will do business as the Auto Inn Garage.

E. W. Fuller has added automobiles to his livery stable on Court street, Dallas, Ore. He has the agency for several popular-priced cars.

James Morton, of Midland, Md., has purchased the blacksmith shop of H. Gantt, in Frostburg, in the same State, and converted it into a garage.

Port Alleghany, Pa. It is to be 40 feet square, of concrete blocks.

Annum Clay, one of the partners in the Remick & Clay Co., accessory dealers in Sacramento, Cal., has sold his interest to William Appleton. The name of the company has been changed to Remick-Appleton Co.

A new company to represent Kline cars has been organized in Philadelphia, Pa., with salesrooms at 514-516 N. Broad street. It will be styled the Kline Kar Sales Co., and will be incharge of L. E. French and W. Wayne Davis.

Amos R. Bliss, of Lowell, Mass., has opened salesrooms in the Ashwell Garage, Chase, with salesrooms at 916 West Walnut street, Des Moines, Iowa. As the name indicates, Rambler cars will form the mainstay of the company.

Len Ormsby and J. F. Mulqueen, both of whom have earned fame as racing men and who are well knodn to trade in the metropolis, have formed the Blitzen Sales Co. to handle the Blitzen engine starter

Digitized by Google

and also to deal in automobiles and accessories generally. They have located at 1777 Broadway, New York.

The Kelly-Damon Auto Supply Co. has been formed at Brocton, Mass., for the purpose of conducting an accessories and supplies business. George E. and George F. Damon and Stephen H. Kelly are the men concerned in the enterprise.

The E. S. Sporting Goods and Auto Supply Co. is the style of a new concern which just has opened up at the corner of Clayton and Lumpkin streets, Athens, Ga. L. E. Scott and W. S. Eberhardt are the partners, whose initials form the name of the company.

Ray H. Reid and Lee Hall have formed the Southern Motor Car Co. and established headquarters at 425 West Forsyth street, Jacksonville, Fla. They will do general garage and repair business and expect later to take the agency for several low priced cars

The W. B. Guyton Tire & Rubber Co. has been organized in Los Angeles to handle Swinehart tires in Southern California and has located at 1013 South Main street. Huber Rasher is president of the cimpany, W. B. Guyton, vice-president and treasurer, and R. V. Terry, secretary.

Christian Science last week gave way to automobile repairing in Wausau, Wis., when T. H. Jacobs purchased the Christian Science church in that town and converted it into a garage. The structure is a typical brick church, tower and all, and Jacobs expects the nover sight to bring him a lot of trade.

John W. Swan has taken the agency for Reo cars in San Francisco, Cal., and established offices in the Reo building on Fulton street, near Van Ness avenue. The retail sales of Reo cars formerly were handled in San Francisco by the Reo Pacific Co., which retains the coast distributing and wholesale end of the business.

Alleging that Otto Goetz, of Iowa City, Iowa, sold him a half interest in the former's automobile business for $2,500 when that half interest was worth only $950, Adam Scheetz, of the same town, has filed suit against Goetz for $1,500 damages. Until recently Goetz and Scheetz operated a garage and salesroom in Iowa City.

Edmund B. Aymar and Harold H. Bradley, both of Montclair, N. J., have formed a partnership and opened temporary salesrooms at 237 Halsey street, Newark, N. J., where they will show Stearns-Knight cars. A permanent home for the firm now is in course of construction at 299-307 Central avenue, and will be ready on May 1.

Recent Losses by Fire.

East Orange, N. J.—John J. Meyer's garage, 494 Main street, and one car destroyed.

Brooklyn, N. Y.—Joseph Michael's garage at Smith and Warren streets destroyed; loss, $25,000.

SUES BANKRUPT FOR COMMISSIONS

Demotcar Sales Co. Loses First Round but Appeals—Terms of the Contract That is Involved.

Involving a claim for $22,789, the suit of the Demotcar Sales Co., of Detroit, against the bankrupt Demotcar Co. just has been decided by the United States District Court for the Eastern District of Michigan, at Detroit, in favor of the bankrupt. The claimants, however, are not satisfied, and have carried the case to the United States Circuit Court of Appeals for the Sixth District, which sits in Cincinnati.

The suit is one of the numerous sort involving the payment of commissions, and is somewhat unusual in that it is leveled against a bankrupt concern and involves a contract that appears to have left much unsaid. The contract, entered into in 1909, whereby the Demotcar Sales Co. undertook to market the output of the Demotcar factory, the selling price of its car being fixed at $550, and a deposit of $15 being required from each purchaser, which deposit was paid to the manufacturer. In return for its service, the Sales company was to receive 20 per cent. of the deposits and 20 per cent. of the remainder of the purchase price when it was received by the Demotcar company.

The Sales company actually obtained orders and deposits for more than 3,600 cars, but comparatively few of them had been manufactured when the Demotcar Co. went into bankruptcy in August, 1910. The Sales company promptly filed its claim, which consists of two items, one for $1,568.50 for commissions, representing cars delivered and paid for, which was allowed by the referee in bankruptcy. The other item involves 21,218.50, representing commissions on orders which the Sales company had secured but which had not been filled, was rejected by order of the referee, who pointed out that the contract between the two companies did not require the Demotcar Co. to deliver any car to any purchaser, and that it contained no provision for any breach in any condition of the contract. Despite this apparently convincing argument, the Demotcar Sales Co. applied to the courts and, undiscouraged by its loss of the first round, is still fighting for what it believes is its due.

Bay City Gets Another Truck Factory.

The Wenonah Motor Truck Co. has been organized in Bay City, Mich., and will be incorporated under the laws of that State, probably during next week. A. B. Perkins, a prominent commission man of Bay City, and his three sons, together with G. E. Porter, an experienced automobile man from Detroit, are the men concerned in the enterprise, of which A. B. Perkins will be president, C. R. Perkins, secretary and treasurer, and G. E. Porter, manager and chief engineer. A factory already has been secured in Bay City, at Eleventh and Saginaw streets, which affords 25,000 square feet of floor space, which quarters, however, are of a temporary nature, as the the building of a modern factory is in view.

The company will produce trucks of 1,000, 1,500 and one ton capacity, the first output being of the 1,000 pound type It will employ a four-cylinder unit power plant, sliding gears, thermosiphon cooling, with fan in the flywheel. The 20-horsepower motor will be located under the hood in front. Ignition will be by Bosch high tension magneto with fixed spark. Lubrication will be by splash.

Court Now Hearing Nobby Tread Appeal.

The appeal of Morgan & Wright, of Detroit, Mich, against the decision of Judge Lacombe in the famous "Nobby Tread" suit at present is being argued in the United States Circuit Court of Appeals for the Second Circuit, in New York City. As will be recalled, the Republic Rubber Co., of Youngstown, Ohio, charged Morgan & Wright with infringement of the Tod J. Mell patent, No. 898,907, on staggered treads for automobile tires, and Judge Lacombe last October decided in favor of the Republic company, holding the patent infringed. He granted an injunction but suspended it pending the outcome of the appeal to the higher court.

Sues "Unlicensed" Seller of Spit-Fires.

In line with their action in similar instances of unlicensed sales of their Spit-Fire spark plugs, A. R. Mosler & Co., of New York City, on Friday last, 29th ult., filed suit in the United States District Court for the Southern District of New York against the American Auto Supply Co., of 1697 Broadway, New York, asking for an injunction and accounting. The complaint charges infringement of the Mosler patents, Nos. 698,042 and 738,831, by offering for sale Spit-Fire plugs without a license or permission from the patentee.

Van-L Truck Passes Into New Hands.

The Commercial Service Truck Co., capitalized at $175,000, has been organized in Grand Rapids, Mich., to take over the business of the Van-L Motor Truck Co., which occupies a factory building in that city. The officers of the new company are Philip Moran, president; J. W. Landman, vice-president, and G. H. Greenbauer, secretary. Of the capital stock, $112,000 has been subscribed, and the remainder is offered for sale in order to increase the working funds.

Lewis Departs to the Pacific Coast.

E. W. Lewis, secretary and treasurer of the Timken-Detroit Axle Co., has departed for an extended vacation, which will reach as far South as New Orleans and as far West at Los Angeles. He will be absent about a month or six weeks.

Subscription, Per Annum (Postage Paid) $2.00
Single Copies (Postage Paid) . . . . . 10 Cents
Foreign and Canadian Subscriptions $3.00
Invariably in Advance.

Postage Stamps will be accepted in payment for subscriptions. Checks, Drafts and Money Orders should be made payable to The Motor World Publishing Co.

☞ Change of advertisements is not guaranteed unless copy therefor is in hand on SATURDAY preceding the date of publication.

Contributions concerning any subject of automobile interest are invited and, if acceptable, will be paid for; or, if unavailable, will be returned provided they are accompanied by return postage.

Cable Address, "MOTORWORLD," NEW YORK.

Entered as second-class matter at the New York Post Office, November, 1900.

NEW YORK, APRIL 4, 1912

TEMPERING CLEAN DESIGN WITH ACCESSIBILITY.

It is not inconceivable that in course of time the progress made in the design and construction of automobile motors will have reached such a state of development that it rarely will be necessary to give them much more attention other than the replenishment of oil, fuel and water tanks.

In the present state of the art, however—and things must be dealt with as they are, and not as they may be in the future—motors cannot be so built that they will not require more or less frequent attention, especially in commercial vehicles, and often such attention is entailed at times when facilities for doing the necessary work are limited and time presses. In such cases the motor the parts of which are the most accessible, must win advocates, even though its design may not be the acme of compactness and smoothness. In other words, accessibility is of more importance than mere appearance or compactness, and will continue to be so until motor engineering has reached a considerably higher level than that on which it now stands.

Within the last year or two a great deal of attention has been bestowed upon the production of compact motors of what is termed clean design, and to the reduction of noise. While in many cases remarkably good results have been attained, in some instances there is a distinct tendency to jumble parts together in such a way as to make it a matter of the utmost difficulty to reach those parts that are most likely to require attention. Exhaust and intake manifolds sometimes are so placed as to make the removal of valves a task of magnitude; pumps have been placed so they are difficult to find, to say nothing of removing them for repairs; valve stems and springs have been covered—for the purpose, laudable in itself, of muffling noise—so that it is an unpleasantly difficult matter to uncover them; and so on. Obviously this is not as it should be, and though the objects sought in tucking things away out of reach are intrinsically right, it still is necessary that compactness and clean design should be tempered with accessibility.

ROOM FOR LANDAULET TYPES OF BODY.

Just because the number of cars that were kept in commission during the past cold months was greater than ever before does not necessarily mean that the individual motorist gradually is becoming more immune to the rigors of winter weather on the highway. But it does point conclusively to the fact that the day of "all year" motoring surely is drawing nearer. Which leads to the conclusion that the practice might be fostered by the simple expedient of supplying a type of body that is more suitable for all weather use than are existing types—a body which will provide warmth and protection in winter and protection without warmth in summer.

With all due credit to the wisdom of those who have made the utterances, there really are few if any sound reasons for maligning the landaulet body. It is quite true that the landaulet body is far from perfect. But such bodies and the recently developed convertible bodies, which one minute may be a closed car and the next an open car, as open as all outside, are a step in the right direction and the wonder is that there is not a greater number of them in use. Their cost naturally militates against them for the use of the average motorist of average means, but it appears that there is room for improvement—that a body of this type might be produced at a moderate cost and supplied as "stock" on moderate priced cars. At any rate, the number of such moderate priced convertible cars abroad surely is increasing and there is even more reason why they should increase on this side of the water. Runabouts and touring cars are all right as far as they go, but they do not go far enough, or, at any rate, not comfortably enough, when the chill of winter is in the air or when the floodgates of heaven are opened.

FRELINGHUYSENISM AND THE FRUITS THEREOF.

Conceived in a narrow, grasping spirit, as those intimately familiar with the subject are well aware, it was inevitable that sooner or later the legislative conscience of New Jersey would be quickened and that that State would rid its system of the bile that had been injected into it and again become an integral part of the Union. The Chinese wall which Joseph Frelinghuysen built around the State which he served as a senator while actually living in New York, and which just has been torn down, injured New Jersey and New Jerseymen more than all others. In mere dollars and cents, their loss has been incalculable; in prestige and personal comfort the loss has been even greater. While New Jersey at last is well rid of Frelinghuysenism, more than a generation will be required to overcome the moral effect of what that term stands for; and if it stands for anything it stands for the gross perversion of so-called State rights. This is one country and "reciprocity" between any of the component parts of it should be unnecessary.

BENNET SOUNDS NOTE OF WARNING

General Motors' Export Manager Points Out Danger of Scramble for Foreign Trade—Fears Overstocked Market.

O. G. Bennet, vice-president of the General Motors Export Co., who just has returned from a European trip, speaks interestingly of the progress made by American manufacturers in exploiting their product in England and other foreign countries, and, while not pessimistic, sounds a note of warning that is worth heeding.

"There has been so much optimistic talk of late in regard to our export trade in motor cars that it is time the conditions as they exist should be known," he says. "It is true that the number of cars shipped from this country is steadily increasing, but analysis of the situation develops that our increased business during the past few months has been done chiefly with England.

"The indifference on the part of the American manufacturer to the English market during the past few years seems to have been supplanted by a wild rush for business in that country. In consequence, the pendulum has swung so far in the other direction that much harm may be done to American trade during the next few months by the overstocking of goods as was ever done by neglect in the past.

"The English market consumes in the neighborhood of 40,000 medium priced cars yearly, so the total number shipped from the United States makes a small percentage. The number of Englishmen who will buy American cars and be willing to have their friends know it is growing constantly, but as far as I have been able to ascertain the number of shipments now taking place are not orders but consignments. In some instances dealers have small deposits on a number of orders, but most of these cars are awaiting purchasers.

"The General Motors business in England is in a very healthy condition. We are selling to our British cousins just what they want. They have their own ideas regarding bodies and finish, and we are willing that they should buy those of English design for application to our chassis, which they find, price considered, far superior to their own make, and it follows that we believe this the proper policy to pursue."

Norwalk Now Seeks Men With Money.

Grown philanthropic, the 35% Automobile Supply Co., of New York, which is practically another name for A. B. Norwalk, is reaching out in a new direction in its get-the-money campaign. Through the medium of conspicuous advertisements in local papers, he is offering a "Big Business Opportunity for the Right Man," the opportunity consisting of a chance for "the right man" to "invest $5,000 or more" in a branch store which Norwalk says he desires to establish "right on the ground with the right man at the head of it." Despite the fact that most men with "$5,000 or more" are inclined to invest it on their own accounts, Norwalk apparently believes there are enough of them anxious to get in touch with him, and for some reason he desires that they address their letters to him personally and not to his company.

Imports Show Renewed Activity.

Imports of automobiles into the United States during the month of February, 1912, for the first time in nearly three years showed increased shipments from each of the four leading automobile manufacturing companies of Europe, the total figures for the month amounting to 73 cars, valued at $166,048, as compared with 41 cars, valued at $104,924, in the same month of the preceding year, representing a gain of 76 per cent. in quantity, and 60 per cent. in the value of the cars. The respective quantities are as follows:

Imported from	No.	Value.	No.	Value.
United Kingdom..	10	$30,158	21	$45,278
France	21	46,813	40	101,696
Germany	1	2,856	4	4,854
Italy	2	4,050	6	9,818
Other countries..	7	21,047	2	4,402
Total cars.....	41	$104,924	73	$166,048
Parts of.....		16,716		29,241
Total cars and parts		$121,640		$195,289

The gains registered during the first two months of 1912 served to boost the figures for the eight months ending February, 1912, above those for the same period of 1911, the records showing that 717 cars, valued at $1,572,376, were received, as compared with 586 cars, valued at $1,250,144, last year. Parts to the value of $212,195 and $212,245, respectively, were imported during these periods, bringing the totals for cars and parts to $1,784,568 in the eight months ending February, 1912, as against $1,462,389 in the same period ending February, 1911.

Clayden "Clocked" for His Courtesies.

Arthur Ludlow Clayden, the member of the British Institution of Automobile Engineers, who attended the meeting of the American Society of Automobile Engineers in Dayton, Ohio, last summer, and who inspired the visit which the S. A. E. party paid to England later in the year, has received tangible evidence that his many courtesies have not lacked appreciation. The members of the S. A. E. who made up the party have purchased by subscription and presented to Clayden a Waltham chronometer which will prove a handsome and useful desk ornament. The case in which the chronometer is enclosed bears a plate suitably inscribed.

Neumann Heads the Detroit Dealers.

William F. Neumann, of the Neumann-Lane Co., was elected president at the annual meeting of the Detroit Automobile Dealers' Association on Monday last, 1st inst. The other officers chosen are as follows: H. B. Moran (Chalmers), vice-president; Joseph A. Schulte (Cadillac), secretary; C. C. Stockweather (Buick), treasurer; Paul R. McKenny (Brush), director. Preceding the election, which occurred at the Log Cabin Inn, dinner was served.

April 6-8, San Antonio, Tex.—San Antonio Automobile Club's reliability run.

April 13, New York City—Annual Motor Truck parade under the auspices of the New York Motor Truck Club.

April 14, San Jose, Cal.—Track races promoted by J. Alex. Sloan.

April 29-May 4, Burlington, Vt.—Burlington Merchants' Protective Association's annual show in State Armory.

May 4, Santa Monica, Cal.—Santa Monica road race.

May 15-18, Chicago, Ill.—Chicago Motor Club's reliability run for commercial vehicles.

May 30, Indianapolis, Ind.—Five hundred miles International Sweepstakes race on the speedway.

May 30, Salem, N. H. — Rockingham Park track races.

June 8, Narberth, Pa.—Track races under the auspices of Quaker City Motor Club.

June 20, Chicago, Ill.—Chicago Motor Club's annual hill climbing contest on Algonquin Hill.

S. A. E. to Locate in Rubber Building.

On or about May 1st the New York headquarters of the Society of Automobile Engineers will be removed from their present location, 1451 Broadway, to the new 20-story building of the United States Rubber Co., at Broadway and 58th street, which is nearing completion. The S. A. E. will be located on the 12th floor, and its quarters will be sufficiently ample to permit of salesroom and library, business office, secretary's office and stockroom.

Mott Puts Flint Socialists to Rout.

C. S. Mott, the active manager of the Weston-Mott Co., of Flint, Mich., was elected mayor of that city on Monday last, 1st inst., by a majority of about 1,800. His election was of more than usual interest in that he was opposed by a cigarmaker on the Socialist ticket, who opposed Mott not as an employer of labor but because he was alleged to represent what were termed corporation interests. Mott ran as an independent and carried the entire Citizens' ticket with him.

SCHIMPF RETAINS CHAIRMANSHIP

Patriotic New Yorker Finally Made Permanent Head of A. A. A. Contest Board—Webb, However, Succeeds Stevens.

William Schimpf, ex-president of the Long Island Automobile Club, of Brooklyn, N. Y., will continue, for patriotism and not for pay, to serve as chairman of the Contest Board of the American Automobile Association, which position he has filled since the death of Samuel A. Butler in November last. Schimpf's first acceptance of the position was only temporary, and there were those who for some reason appeared to fancy that a paid chairman might perform better service, but with that queer notion dissipated and now that Schimpf has been formally installed as the head of the board, it is expected that the reins of power will be drawn still tighter and that in the future contests and the operations of the Contest Board will be conducted in an even more strictly businesslike way than heretofore was the case.

Barring the appointment of Schimpf, only one other change in the personnel of the board was made, Frank G. Webb taking the place of S. B. Stevens, who resigned. The other members remain as follows: H. W. Knights, P. D. Folwell, Joseph H. Wood, Charles I. Ryan, David Beecroft, Frank M. Joyce, R. W. Carr, Ralph W. Smith and P. W. Walker. The Advisory Committee remains unchanged and includes S. A. Miles, manager of the National Association of Automobile Manufacturers; H. A. Bonnell, manager of the Automobile Board of Trade, and Jesse Froehlich, representing the importers.

Similarly, the list of State representatives remains unchanged and is as follows: A. M. Kennedy, Alabama; G. P. Bullard, Arizona; P. J. Walker, Northern California; Edward G. Kuster, Southern California; Ralph W. Smith, Colorado; C. H. Gillette, Connecticut; Henry M. Taylor, Delaware; H. B. Race, Florida; Charles I. Ryan, Georgia; R. W. Spangler, Idaho; David Beecroft, Illinois; C. W. Sedwick, Indiana; C. A. Kneedler, Iowa; P. M. Milner, Louisiana; T. C. Campbell, Louisiana; D. W. Hoegg, Jr., Maine; Dr. H. M. Moore, Maryland; H. W. Knights, Massachusetts; Dr. C. E. Dutton, Minnesota; Robert P. Bridge, Mississippi; W. P. M. Stevens, Missouri; W. D. Hooford, Nebraska; C. M. Floyd, New Hampshire; Joseph H. Wood, New Jersey; Frank C. Webb. New York; James R. Gray, Jr., North Carolina; W. J. Price, North Dakota; Nelson B. Ruggles, Ohio; H. L. Keats, Oregon; P. D. Folwell, Pennsylvania; Charles E. Dee, Rhode Island; A. McP. Hamby, South Carolina; H. C. MacCoshen, South Dakota; R. W. Carr, Texas; W. D. Rishel, Utah; W. W. Brown, Vermont; Dr. H. W. Bassett, Virginia; F. M. Fretwell, Washington; T. A. Westmyer, West Virginia; George A. West, Wisconsin.

As the result of several changes of a financial nature which were made in the agreement which binds the Manufacturers' Contest Association and the A. A. A., the relations between the two bodies have become even more closely interwoven than heretofore, the changes having been made as a result of several conferences between President Hooper and Messrs Joyce and Speare, of the A. A. A., and Messrs. Coffin, Marmon, Hollander, Riker, Wagoner, Meigs and Emise, of the M. C. A. As chairman of a special committee from the M. C. A., E. R. Hollander accepted the revised agreement under which operations will be carried on in the future.

Disbrow's One-Mile "Record" Falls Flat.

According to despatches from San Diego, Cal., Louis Disbrow drove a 190 horsepower reconstructed Fiat on Monday last, 1st inst., one mile in 38⅗ seconds, and thereby established a new record for the distance. But for two very excellent reasons the "record" is no record at all. In the first place, the Contest Board of the American Automobile Association does not recognize one-mile circular dirt track records unless they are actually are made on a one-mile circular dirt track. Disbrow drove on a two-mile track. In the second place, the A. A. A. requires that electric timing apparatus be used in the establishment of all records for distances under five miles. Disbrow was "clocked" with an ordinary stop-watch. Consequently, the record for a one-mile circular dirt track still stands at 48.6 seconds, where Burman set it last September at the Brighton Beach track in New York. That Disbrow drove mighty fast there is no doubt, but the fact remains that he is not entitled to a record, nor will he get one for the trial. The meet in which Disbrow drove was sanctioned, the sanction being issued jointly to J. Alex. Sloan, who but recently was reinstated in the A. A. A.; Louis Disbrow and a local newspaper man.

Orders Chauffeurs to Go to School.

The ordinance of the Berlin authorities demanding a special training for chauffeurs in a municipal chauffeurs' school may or may not have come to the notice of the mayor of Boston. If it has escaped his eye, it would seem to indicate that "great minds run in the same channel," as the old saw goes. For last week the Hub's executive issued orders to all department heads employing chauffers to request the chauffeurs to attend the Franklin Union course upon the operation of gasolene engines, which opened on Monday, April 1st. The mayor believes that every city chauffeur who gets a certificate from the Franklin Union should be given an increase in salary, and plainly intimated that unless the chauffeurs took advantage of the course their requests for more pay would not be considered. The course will extend for eight weeks, with three classes weekly.

NEW JERSEY'S WALL DEMOLISHED

Despite Protests, Governor Signs Reciprocity Bill—Exact Text of Law as it Applies to Non-Residents.

Governor Wilson, of New Jersey, attached his signature to the Stickel automobile reciprocity bill on Tuesday last, 2d inst., and thereby, for the first time in five years, that State once more became a land of and for the free. The law took effect immediately, and non-resident motorists, without distinction, now can come and go as they please and without cost for a period of fifteen days in each year. Even the objectionable "power of attorney" clause, by which non-residents automatically appointed New Jersey's secretary of state as their attorney or agent to accept legal service, has been eliminated.

The opponents of the measure died hard. They maintained their objections to the very end, appearing before Governor Wilson at a hearing which he held Tuesday afternoon and voicing more or less indignation and fear, all of which was of the same sort that "Carpetbagger" Frelinghuysen, who was responsible for the miserable law that closed the State, and his kind have brought to bear whenever it was sought to break down the bars which they erected. One of them, described as a farmer, voiced the attitude of the opposition when he declared that New Jersey was giving away everything and receiving nothing in return. When Governor Wilson reminded him that the bill gave to other States just what was given to New Jersey, the farmer raised a laugh when he retorted:

"Well, Governor, if New York permits us to injure and kill its citizens, is that any reason why we should permit citizens of other States to kill and injure ours?"

The automobile interests also were well represented and brought their heavy oral artillery to bear. When the hearing was over the governor promptly signed the bill, thereby making it a law

Assemblyman Stickel, who stood sponsor for the bill, is the youngest member of the legislature, and it is probable that he shortly will be tendered a banquet at which he will be presented the pen which Governor Wilson used in signing the measure. As a matter of fact, the overjoyed automobilists not only secured the pen, but one of them handed the governor a blotter, and, after the executive had used it to dry his signature, tucked it into his pocket and remarked that he intended to frame it as a souvenir of a five-year fight for fair play.

While it gives freedom to non-residents, the law increases the registration fees of New Jerseymen 50 per cent., the new charges being $4.50 for vehicles of less than 10 horsepower; $7.50 for those of from 11 to 29 horsepower, and $15 for those of 30

Digitized by Google

horsepower and over. The full text of those sections of the law which contain the reciprocal features is as follows:

"Any motor vehicle belonging to any person who is a non-resident of this State and who has registered such motor vehicle in and has complied with all the laws of the State, Territory or Federal district of the United States in which he resides with respect to the registration of motor vehicles and the display of registrations numbers, and who shall conspicuously display such registration number as required thereby, may be driven in this State during a period of not exceeding 15 days in each calendar year, or on two or more occasions not exceeding in the aggregate the period of 15 days in any such year, without complying with or being subject to, the provisions of sections 15 and 21 of the act to which this is a supplement; provided, that each day or part of a day during which any such motor vehicle is within this State shall be considered as one of said 15 days; and provided further, that the provisions of this section shall be operative as to any such motor vehicle owned by non-resident of this State only to the extent that under the laws of the State, Territory or Federal district of his residence, substantially similar exemptions and privileges are granted to motor vehicles duly registered under the laws of this State.

"Any chauffeur or driver of a motor vehicle not a resident of this State, who has registered under and complied with all the laws respecting the registration and licensing of chauffeurs or drivers of motor vehicles in the State, Territory or Federal district in which he resides, may, during the period mentioned, and under the restrictions contained in the preceding section of this supplement, drive any such motor vehicle in this State without complying with, or being subject to, the provisions of sections 17 and 18 of the act of which this is a supplement, or any of them; provided, that the provisions of this section shall be operative only to the extent that under the laws of the State, Territory or Federal district in which such chauffeur or driver resides substantially similar exemptions and privileges are granted to chauffeurs or drivers of motor vehicles registered under the laws of this State."

"Keep to the Left" in Canal Zone.

According to an executive order of the United States government, the speed limit for automobiles in the Panama Canal zone has been fixed at 15 miles per hour. Simultaneously with establishing rules governing the speed of automobiles it has been decided to follow the English custom of "keep to the left" instead of to the right, as in the United States and most of continental Europe. Vehicles approaching each other or being overtaken and passed by other conveyances, are required to keep as closely as possible to the left of the road, while those overtaking and passing other vehicles must pass to the right.

MASSACHUSETTS TO RAISE FEES

Increases Advocated by Governor Are Approved by Legislative Committee—Rates for Heavy Trucks Arouse Protest.

Believing that the present fees for automobiles and other motor vehicles are not high enough to compensate for the damage done to highways, the Committee on Roads and Bridges of the Massachusetts legislature has reported in favor of the increase recommended by the governor. If the bill having this change in view goes through, the motorists of Massachusetts will have to pay the following fees: 5-19 horsepower, $4.80; 20-29 horsepower, $11.60; 30-39 horsepower, $19.50; 40-49 horsepower, $36.75, and more than 50 horsepower, $50.

The bill also provides for an increase from $2 to $2.50 in the motorcycle fee, from 50 cents to $1 in the operator's renewal license fee and from $25 to $30 in the manufacturers' and dealers' registration, with $6 instead of $5 for each additional car registered beyond five.

While the opposition to the proposed increase for pleasure cars is not inconsiderable, it is as nothing compared to the hue and cry that is being raised by the commercial vehicle users over the unfairness of the classification. They particularly cite the case of the heavy trucks.

"For example," says Lewis R. Speare, of the Massachusetts State Automobile Association, "some five-ton trucks have 35 horsepower, some have 40 and some 48.6. Each is carrying the same load and at the same rate of speed. Manufacturers agree that 12 miles an hour is the speed that a truck should make, and it should not be driven at a higher rate. If the 48.6 horsepower truck was rated at 49 the fee would be $36.75, the 40 horsepower would pay $30, and the 35 horsepower would pay only $17.50, less than half the registration of the 48.6 truck, while doing equal damage to the road in every respect.

"In other words, the 48.6 horsepower motor truck is obliged to pay more than twice as much as the 35 horsepower truck simply and purely because it has a larger engine. It goes no faster, carries no larger load, and does no more damage to the road.

"We have suggested the following scale for motor trucks, which would make an enormous increase in the amount of registration, and, it seems to us, would be fair: 1-ton, $5; 2-ton, $7.50; 3-ton, $10; 4-ton, $12.50; 5-ton, $15; 6-ton, $17.50; 7-ton, $20; 8-ton, $22.50; 9-ton, $25; 10-ton, $27.50; over 10-ton, $50."

Milwaukee and Dallas Want the Vanderbilt.

Following closely the definite announcement that the Vanderbilt Cup race would not be held in Savannah, Ga., two applications from organizations which are anxious to stage the classic event in their respective localities have been filed with the A. A. A. Dallas, Texas, already had entered its bid, and quite unexpectedly the Milwaukee Automobile Dealers Association, with the endorsement of the Milwaukee Automobile Club, the Chamber of Commerce and the Hotel Dealers' Association, submitted a proposal to conduct not only the Vanderbilt race, but the Grand Prize race, on one of three courses near the city. Each of the three courses in view is about seven miles in extent, and it is claimed by the Association members that the expenditure of about $50,000 would suffice to put either of them in first-class condition and also to erect the necessary grandstands. The Dallas (Tex.) Automobile Club would run the cup race on a course which measures 11 3/10 miles, and which is located at no great distance from the city.

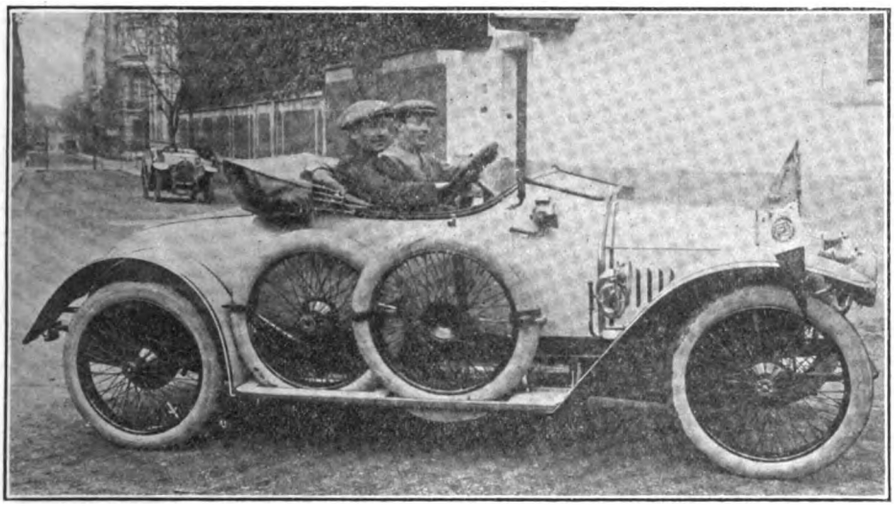
No More Racing at Minnesota Fair.

Though no fatalities nor even accidents marked the two days of automobile racing which added zest to the Minnesota State Fair last year, it is not at all unlikely that the "automobile racing card" will be eliminated from the program when the "event which will make Minneapolis famous" is inaugurated during the week September 2d to 7th. According to officials of the Minnesota Agricultural Society, under the auspices of which the event is held annually, as a certain amount of danger always is attendant upon race meets which are run on dirt tracks, it is deemed wise not to again include speed contests in the program. This is the fifth State fair association which has tabooed automobile racing, Syracuse, N,. Y. Minneapolis, Minn., Spokane, Wash., and Dallas, Tex., having reached similar decisions within recent months.

Anti-Automobile Bills Die with Legislature.

When the New York legislature adjourned on Friday last, all of the several bills inimical to the automobile interests died with it. Among those that expired were the bills requiring the dating of tires, the display of an automatic rear signalling device and the one which proposed the abolishment of automobile racing in New York State. The Callan law was left untouched and unamended. Of the bills favored by the automobile interestes, there was enacted in the closing hours of the legislature one which seeks to provide an additional $50,000,000 for road improvement.

A. A. A. Tour Will End in New Orleans.



It has definitely been decided that the A. A. A. reliability tour heretofore known as the Glidden tour will terminate in New Orleans, the $4,500 guarantee necessary to bring about the selection of the Crescent City having been pledged by members of the New Orleans Automobile Association. The starting point has not yet been selected, but several cities, Detroit in particular, are bidding for the honor.

TOUR DE FRANCE PROVED A JOY RIDE

Fine Roads and Easy Conditions Enable 40 Contenders to Survive—Benz Team Wins — Americans Eliminated.

Although the newspaper-promoted Tour de France, which started from Paris on March 1 and finished in a Paris suburb on March 20 last, after having covered about 2,400 miles of the class of roads for which France is famous, was called a reliability tour, it should have been labeled "joy ride" —for aside from a few minor requirements as to speed limit and classification according to size of cylinders and gear ratio, it was a free-and-easy sort of a run. Which, in a way accounts for the fact that 40 out of the original 67 entrants were able to go the whole route without serious mechanical trouble. The 27 "missing" were not all eliminated by accidents or engine trouble—in several instances being simply ruled "out" by the "racing jury" for infraction of the few regulations that had been formulated.

ONE OF THE BENZ TEAM IN THE TOUR DE FRANCE

The first prize, consisting of a superb art plaque presented by the City of Lyons, went to the Benz team. In awarding this prize L'Auto, which promoted the affair, says: "The performance of this team was a revelation to all; for 4,000 kilometers these silent, powerful and speedy cars never were more than 50 yards apart; they were always on time, had no mechanical troubles of any kind and were voted the most beautiful cars of the whole 67." Medals of gold and silver went to the Corre, Bugatti and the Dumond, which latter was the only single-cylinder four-cycle machine in the contest.

Had it not been for a somewhat strict application of the restrictions as to gear ratio, the three Ford entries would have appeared among the finishers instead of being disqualified, for despite their early disqualification, as reported in the Motor World, they continued as non-contestants. French reports of the disqualification differ in details, but according to the most reliable version of the affair the Ford cars, in negotiating an extremely hilly section of the tour, changed the 32-inch demountable wheels to 30-inch wheels, thereby obtaining a more advantageous gear ratio for hill-climbing. When this change of wheels was called to the attention of the racing jury by a number of the contenders, the latter's protest was sustained and the Ford team was disqualified. As stated above, it finished in good shape with the rest of the cars, though, of course, as non-contenders.

As the organizer of the tour, L'Auto, put it: "The Fords were eliminated on account of an error of judgment on the drivers' part —not because they did not do their work well."

The other American contenders, two Reos and one Hupmobile, were pursued by bad luck, suffering minor mishaps which put them out of the running by delaying their arrival at control stations.

Oldfield's Sentence Suddenly Shortened.

For no apparent reason other than mellowness of spirit, the ban which was placed on Barney (Berna) Oldfield by the Contest Board of the American Automobile Association about two years ago and which would have expired by limitation on July 1st next has been commuted and after April 30th, which is the date set for his reinstatement in good order, he will be able to drive in sanctioned meets without contaminating those with whom he may compete. The disqualification of Ben Kerscher, who was one of Berna's helpers and whose sentence likewise would have expired on July 1st, also was commuted to terminate April 30th, though "Bill" Pickens, Oldfield's one-time manager, did not get off so easily. From an indefinite period his disqualification was definitely fixed to expire on July 1, 1917, by which time it is thought his heels will be well cooled.

NEW YORK TO ELIMINATE CUT-OUT

Aldermen Finally Pass the Prohibiting Ordinance — Will Become Effective 90 Days After Mayor Approves It.

On and after a date which will fall somewhere near the glorious and noisy Fourth, there will be less noise in New York than now is the case, if, as seems probable, Mayor Gaynor affixes his signature to the ordinance forbidding the most unnecessary of street noises, that caused by the muffler cut-outs, which was passed by the Board of Aldermen at its last meeting, on Tuesday, April 2d. The measure, which was introduced by John H. Boschen, becomes operative 90 days after receiving the mayor's signature; the mayor is allowed 10 days in which to append his name.

Briefly, the ordinance provides that every motor shall be equipped with a muffler or silencer through which all the exhaust gases must pass, and prohibits the use of a muffler cut-out or any device that will permit the exhaust gases to escape into the asmosphere without first passing through the muffler. Violations are to be punishable by fine or imprisonment, the minimum being $10 or 10 days.

In this connection it is not generally known that some four years ago a measure of similar import to the one just passed was drafted and handed to Alderman Mulcahey, who at that time represented the district which Boschen now represents, and who professed to be enthusiastically in favor of it. It was quietly pigeonholed, however, and when pressed for the reason for his inaction Mulcahey threw the blame on the aldermanic law committee, which, he stated, declared the proposed ordinance to be illegal and prevented its introduction.

The text of the Boschen measure is as follows:

"Section 1. Every motor vehicle propelled by an internal combustion engine, when such vehicle is on any street, road, avenue, alley, park, parkway or public place within the city limits, shall, when such engine is running, be equipped with a muffler or silencer, through which all or the exhaust gases from the engine will escape into the atmosphere.

"Section 2. It shall be unlawful for the operator or driver of any motor vehicle to use any cut-out, fitting or other apparatus, or a device which will allow the exhaust gases to escape into the atmosphere without passing through a suitable muffler or silencer as described in section 1.

"Section 3. Any person violating the provision of this ordinance, may, upon conviction thereof by any city magistrate, be fined a sum not exceeding $10, and, in default of payment of such fine, may be committed to prison by such city magistrate until the same be paid, but such imprisonment shall not exceed 10 days

COUPE-LANDAULET BODY APPEARS

Type Much in Vogue Abroad But Seen Here Only in Taxicab Form Finally Finds Sponsor—Its Features.

Though the inside driven coupe which but recently has sprung into prominence fills in a measure the popular demand for an "all weather" type of body, it still leaves something to be desired. When the windows are closed it becomes a closed car in every sense of the word, but when the windows are opened it does not become an open car to the extent that might be desired. The landaulet offers a partial solution of the problem, but there are those to whom the landaulet does not appeal either by reason of its size, which increases upkeep cost, or because the owner cannot drive the car and at the same time be protected from the elements. It is to bridge the gap between the coupe and the landaulet that the R. J. Irvin Mfg. Co., the Indianapolis body maker, has brought out what is styled the Irvin coupe-landaulet, a type of body which is much in vogue abroad and which is shown by the accompanying illustrations.

In perfecting the new body the comfort of passengers has been maintained as of prime importance, as a matter of course, and to this end the upholstery has been given unusual attention with a view to producing the easiest riding qualities possible. In addition to the usual curled hair, the cushions are rendered even softer and more luxurious than usual by the insertion of extra long coil springs. Another feature which is worthy of remark is that the doors have been made unusually wide, the sills measuring 26 inches. The provision of abundant storage space likewise reveals careful designing and forethought. Under the seat, which is 50 inches wide and therefore seats three passengers without undue crowding, there is space sufficient to store two suit cases. The back upholstering of the seat is arranged to swing outward on hinges and discloses a roomy cupboard suitable for the carrying of robes or clothing, which may be hung on hooks, and also spare tubes and tools. Numerous shelves are provided for the reception of small articles, and at each side there are two circular spaces in which Thermos bottles may be carried right side up. Additional storage space is provided at the back of the body in a compartment which also contains a 20-gallon gasolene tank.

Entrance to the compartment is effected by means of a wide door at the back. Spare tires inflated and carried on demountable rims are carried at the rear, over the compartment, and are held in place by means of special tire irons.

IRVIN COUPE-LANDAULET BODY CLOSED AND WITH THE BACK LET DOWN

Municipality Establishes Chauffeur's School.

With the intention of increasing the efficiency of German chauffeurs—in particular that of Berlin chauffeurs—the city of Berlin, Germany, has taken a step which wiwll be watched with the greatest interest by all other large cities of Europe. It is nothing less than the establishment of a municipal school for chauffeurs, in which every person who hereafter applies for a driver's license in Berlin, will be required to pass through a stated training course. As far as equipment is concerned the new institution will be second to none in the world, no less than six of the leading automobile factories of Germany—Benz, Daimler, Adler, Stoewer, N. A. G., and Siemens-Schuckert—having presented new cars to the school, while the Association of Motor Vehicle Manufacturers has given a full line of motors, parts, carburetters, etc.

One New Truck Appears at Geneva Show.

Amid a setting embracing the usual abundance of tinted bunting and glowing electric lights, a comprehensive display of motor vehicles, both pleasure and commercial, was staged in the Geneva (N. Y.) State Armory from Thursday evening, March 28th, until Tuesday, April 2nd. The rather inclement weather which prevailed on the opening night in no wise blighted the size of the crowd which turned out to view the display, which was held under the auspices of the Geneva Automobile Club. Interest attaches to the fact that in this rather conservative array, 21 different makes occupied the booths of the 21 exhibitors, one truck not heretofore exhibited, should appear. It was the Geneva, produced by the Geneva Wagon Co. It is of conventional design, is of 20 horsepower and sells for $1,345. Among the exhibitors were A. V. Hart, Krit and Everitt; Stacey & Jones, Elmore; Geneva Automobile Co., Pierce-Arrow, Buick and American; Auto Sales Co., McIntyre pleasure and commercial; C. O. Hagenbeck, Maxwell; George Goodelle, Reo; H. A. Wagner, Oakland and Rambler; A. McNall, Peerless and Rauch & Lang electric; Abbott-Detroit Sales Co., Abbott-Detroit; Cutting Sales Co., Cutting; E. C. Patterson, Davis; Yells & Schnirel, Overland; A. M. Zimbrich, Stoddard-Dayton and Haynes; Geneva Wagon Co., Geneva commercial.

"Rounding Up" Trucks for the Parade.

As the date approaches for the New York commercial vehicle parade, which has been made a spring fixture by the Motor Truck Club, the members of that organization are bending all their energies to the task of making the showing a representative one and one that will eclipse its previous effort in that direction. The parade takes place on April 13th, starting at 2 P. M., and if the weather gods smile, it cannot well fail to be an improvement on last year's, when a downpour of rain made the turnout a dismal affair.

Nast Assumes "Touring Club" Presidency.

Conde Nast, who recently was elected president of the Class Publishing Co., of New York, has assumed the presidency of the so-called Touring Club of America, which is owned and controlled by the Class Publishing Co. The Touring Club of America is a convenient title which is employed to promote the sale of the road books and road maps issued by an offshoot of the publishing company.

THE DETERMINATION OF CARBURETTER EFFICIENCY

Lack of Knowledge of True Engine Characteristics That Precludes the Possibility of Making Comparative Tests of Real Value—Peculiarities of Altered Efficiency That Obtain Under Different Running Conditions Revealed by Laboratory Tests.

How often has one person made the assertion that with a particular carburetter gasolene consumption is nothing short of remarkable for its smallness only to be contradicted by some one else having identically the same car and carburetter whose gasolene bills are considerably higher?

Leaving aside the irrefutable fact that gasolene consumption depends to a great extent on the expertness of the operator in adjusting his carburetter and the speed of the car, and considering only the relative efficiency of the carburetter as indicated by the actual amount of gasolene converted into power, that this factor for even the same carburetter may vary over exceedingly wide limits according to the speed of the engine to which it is attached has been definitely determined in a more than ordinarily conclusive manner.

The determination was made in a series of carburetter tests which were made by Messrs. R. W. Noland, G. P. Rettig and J. A. Saurs at the School of Mechanical Engineering of Purdue University, of Lafayette, Ind. The tests form the basis of a paper entitled "Some Tests on Carburetters," which was read before the American Society of Mechanical Engineers and it is doubtful if ever before so much light has been shed on the otherwise dark subject of carburetter efficiency.

Before delving into the significance of the tests, George W. Munroe, who presented the paper, first outlines the problem of carburation for automobile engines and points out the difficulties met in determining the performance of a carburetter as distinct from the performance of the engine to which it is attached. Though his opinions scarcely are new, their reiteration may serve to emphasize the fact he later brings out, namely, that there is real necessity for the maintenance of a testing plant "the constants of which are well determined."

"The peculiar features of the problem are that a carburetter is used only in conjunction with an engine and so properly should be tested upon it, thus introducing engine characteristics into the result," he says. "Again, the engine requires a carburetter for operation, and so its performance cannot be determined free from carburetter factors. From this it appears that the two must be tested together, and the securing of a proper standard for comparison of results is most important.

"As the best performance of the engine marks also the best possible carburetter action, the complete determination of the engine characteristics would establish a basis for comparing the behavior of any carburetter which might be used. Owing, however, to the fact that the charactertis-tics of some carburetters are always superimposed on those of the engine, the limitations due to such purely engine factors as compression, shape of clearance space and friction, cannot readily be determined. However, if an engine were tested under the same running conditions with a large number of carburetters, some one of them might furnish a perfect mixture and the best possible performance of the engine would be realized. The repetition of this process with a large number of running conditions would ultimately result in defining completely the engine performance."

To achieve the results which are given in the accompanying table, six carburetters were tested under identical engine conditions through a range of 10 speeds, from 300 to 1,200 revolutions a minute. The

Efficiency based on assumed fuel value of 20,700 b.t.u. per lb.

TABLE SHOWING THE VARYING EFFICIENCY OF CARBURETTERS AT DIFFERENT ENGINE SPEEDS

Digitized by Google

tests were made on a four-cylinder Rutenber engine having a bore and stroke of 4½ inches and 5 inches, respectively, and at each speed tests were run with 10, 20, 30, etc., pounds net load on the brake up to the maximum which could be carried, making some 80 tests with each carburetter.

Though the greater part of the paper is quite technical in its nature and as such perhaps might serve but to bore or confuse the average mind, the accompanying table is a sermon in itself and serves to to indicate conclusively that though one carburetter may show remarkable efficiency —which, as has been pointed out, means the actual value of the fuel divided by the actual power developed—at one engine speed, it may show a woful lack of efficiency at almost any other speed; which leads to the conclusion that the carburetter which will permit an engine to develop the greatest possible power at maximum speed, with comparatively low gasolene consumption may have very much lower efficiency at normal speeds. In other words, it is essential that for economy a carburetter be chosen with due regard to its efficiency at the speed at which the car is to be driven. Barring this, the carburetter which shows the greatest average efficiency at all speeds will be the most economical.

For instance, referring to the accompanying table, carburetters A, B and C show greatest efficiency, which means the least amount of gasolene consumed in pounds (a pound being approximately a pint) per horsepower delivered, at 1,200 revolutions a minute. Carburetter D, however, shows greatest efficiency at 1,000 revolutions per minute, though the greatest power is developed at 1,200 revolutions per minute; the efficiency, however, drops off at the higher speed. Carburetter D, therefore, is the most economical to use at 1,000 revolutions per minute.

Another peculiar fact disclosed by the table is that though carburetter E permits the maximum power obtainable to be realized its efficiency is considerably lower than is that of carburetter C. Similarly, though carburetters C and D give exactly the same maximum power—32.552 horsepower—their efficiencies differ by 6.7 per cent. It is obvious which of the two should be chosen for economy. The average efficiencies of the six carburetters in the order in which they are named in the table are as follows: 16.12 per cent., 14.40 per cent., 15.89 per cent., 16.27 per cent., 17.02 per cent. and 16.42 per cent. Carburetter E, therefore, shows the greatest average efficiency, though at lower speeds the efficiency is very considerably lower than that of some of the others. The average efficiency of all the carburetters, which may be taken as a fair average figure for the efficiency of all carburetters, is 16.20 per cent.

"A consideration of the results obtained," says Monroe, in summing up, "leads to the following conclusions:

"(a) Under identical conditions of speed and load an engine gives materially different fuel economy when served by different carburetters.

"(b) Carburetter action is the limiting factor in engine capacity as well as in economy.

"(c) Wide range and perfect operation give no indication of fuel economy.

"(d) Each carburetter has distinctive performance characteristics which may be determined and plotted.

"(e) The characteristic may be such that a carburetter giving excellent results under some conditions may give very poor economy over a large part of its range.

"Being the limiting element of engine capacity and economy, the carburetter is a machine of great engineering and economic importance and as such demands more scientific methods in its development than have yet been applied. This would necessitate systematic testing and comparison, not only of widely different types, but of the same carburetter after minor changes in design.

"A method of testing carburetters which would be independent of engine characteristics is much to be desired, as then results obtained by different experimenters in different places could be compared. Lacking such a method, it seems desirable that an engine be properly equipped and placed in some laboratory for the testing of carburetters, thus establishing, after the engine characteristics became thoroughly known, a definite standard available for reference. Such a standard would be valuable only in case carburetters retain their relative characteristics when transferred to different engines, which seems probable but has not yet been established experimentally.

"This would require a large expenditure, both for plant and for operation, and, undertaken as a commercial venture, would probably be attended with financial loss. Engine builders, however, spend vast sums each year in developing and perfecting their output, and when the dependence of the engine on the carburetter is considered it would seem that several engine manufacturers might profitably unite in the systematic improvement of the carburetter. Several States have established engineering experiment stations where problems of importance in the development of industries or the conservation of important natural resources may be thoroughly investigated, and the carburetter, important in both aspects, may properly receive their attention."

Bogus Checks Land Canadian in Jail.

With a penchant for inflicting his unwelcome visits upon automobile dealers, Robert McKay Oliver, a young man from Toronto, with a pronounced English drawl, has been making things lively in Buffalo, N. Y. During the past few weeks a number of that city's dealers have been victimized by the distinguished-looking Canadian, whose specialty was the purchase of runabouts and roadsters and paying for them with bogus checks. Not that he succeeded in getting the cars themselves, but on the strength of his deposit of a $500 check "on account" he obtained innumerable "demonstration" rides, during which he stopped at high-class tailoring establishments, where he gave bogus checks for clothing he had ordered and collected the change in real money. His activities finally became so involved and varied that no less than twenty complaints reached the police in a single day, with the result that he was taken into custody and held for trial on charges of attempted grand larceny.

Horns Attuned to Musical Chords.

From a small beginning in a small place, the Minerva exhaust horn has been developed and improved from time to time until the 1912 line comprises a wide range of styles and sizes, all, however, embodying the same fundamental principles and all giving clear musical combinations of notes, varying according to the size and number of pipes employed.

The horn, made by the Minerva Hardware Mfg. Co., of Minerva, Ohio, is of the type which is attached to the exhaust pipe at the discharge end of the muffler. It is made with either three or four pipes, each pipe producing a distinct note of its own, and all perfectly tuned so as to give correct musical chords and requiring so little power that it is claimed that lung pressure will sound them. In fact, the maker goes so far as to state just what notes are produced by given pipes, so that the prospective purchaser can, if he chooses, play the chord on his piano and see if he likes it before buying—and, incidentally, the horns are sold on the "money back" plan. The material used for the pipes is heavy gauge brass tubing and the construction throughout is substantial.

English as it Comes from England.

"We summon from the 'motor house' our new 'two seater' or 'get-a-bout' and watch with some pride as it gracefully draws up to the 'kerb.' It is a 'well sprung' little car and fully equipped with 'vibration absorbers.' Other notable 'fitments' are the friction 'windscreen,' 'hood' (top) and 'bonnet' (hood). Clamped to the left 'step-board' is an extra 'tyre' with anti-skid 'cover.'" They are great on "oddments" in England, as the foregoing description of the latest "8 Guinea Tax" car serves to show. It can do a "flying mile" faster and on less "petrol" than many more costly cars and without opening the "silencer." The car can now be had with detachable "dickey" at a really modest "inclusive" price if purchase is made before date of "expiry" of the offer.

"Economizer" Coming from Poughkeepsie.

The Motor Attachment Co. has been organized in Poughkeepsie, N. Y., by Henry Schrowang, George J. Callahan and Albert Iber, who have in view the manufacture of a gasolene economizer. The company is a partnership and not a corporation.

FORESHADOWS OF THE FAR-DISTANT FUTURE

Budding Engineer Peers Into the Future and Discerns Several Radical Changes in Automobile Practice That May Come to Pass—Among Other Things He Sees Governors on Pleasure Cars and Injection of Liquid Fuel and Pictures Their Advantages.

"It certainly is remarkable with what rapidity the order of things changes," remarked the Designing Engineer's second assistant, with not a trace of that temerity, or tidimity or modesty he was wont to display when discussion waxed warm.

"How so? What's on your mind now?" queried the man from downstairs.

"Well, just glance over the history of the development of petroleum distillation and notice what was done with the lighter distillates, with the naphthas, the gasolenes, the benzines, at the period just previous to the adaptation of the internal combustion engine to the use of liquid fuel. All of these lighter distillates were more or less of a drug on the market; they were used to some small extent in the arts owing to their solvent properties, but the supply greatly exceeded the demand and the price was exceedingly low even for the rectified products, while the crude products, or those which were not purified by redistillation, were considered as waste by the producers. True, a few of the producers used vast quantities to dilute the first marketable distillate kerosene—but the laws enacted prohibiting the sale of kerosene which was below the flash test limit put more or less of a check on this practice.

"The introduction of the carburetting devices and consequent widening of the scope of application of the internal combustion motor so as to make possible its use in isolated places—that is, in districts remote from the city or town and where gas is not likely to be supplied—had a decided effect on the price of the lighter oils. Then came the introduction of self-propelled vehicles—vehicles using liquid fuel in a regular steam engine or in an internal combustion motor. Motor boats propelled either with a steam engine so modified as to use the vapor of naphtha or gasolene in the cylinders or an internal combustion motor entered the field of the gasolene users at about the same time; the lighter products received another boost in price and the average value has steadily been on the increase ever since. Nowadays the lighter products are diluted with the heavier oils; however, this is not done for purely mercenary reasons, although there is a considerable difference in the price of the two products, and this in favor of the gasolene. The adulteration of the gasolene with the lighter grades of kerosene raises the flash temperature and thus renders the product safer for universal usage.

"The steady and non too gradual increase in the price of the only universally employed liquid fuel ought to set to thinking every person interested in the automobile trade and cause them to guess when the limit will be reached, what the limit will be, what will be used when the supply falls short of the demand. Personally, every time the papers announce an advance in the price of gasolene I indulge in one long sweet dream. At such times I can see the more than one hundred and one ways which are not now taken advantage of for the conservation of the supply of liquid fuel. And among the one hundred and one there are two which always stand out prominently."

"Only two?" queried the man from downstairs, with a trace of irony in his tone which wholly was lost on the designer's assistant, now warmed to his theme.

"Well, very much depends on the driver. In England the price of gasolene is nearly double what it is in America—yes, it is a little more than double at the present time—and yet, unless I am far wrong, it costs little if any more to operate a car in England than it does right here. What's the matter? Why, simple enough: It's the American temperament. British cars are no more perfected in design than are our cars; there is no more refinement in detail over there than is shown in the construction of American cars; their motors show no greater thermal efficiency than do the motors of our native heath, and yet they can go about double the distance on a gallon of gasolene. There are only two reasons that I can see why this should be the case. First, because of the prohibitive tax on the higher powered cars the average English automobile is light and low powered; and, second, the average English car owner prefers to travel at a uniformly moderate pace and does not accelerate the the machine to 60 miles an hour and then retard it to 20 miles the next moment. There is not the slightest doubt that were an American car matched with a car of British manufacture, the cars being of equal weight and power and both provided with careful drivers, the average gasolene consumption per mile would vary but slightly. But the American desire for speed, the American's so-called pride, which will not allow of another car passing him on the road, causes the operating and maintenance costs to mount high. However, the usual run of car owners have the idea that a motor car is an expensive proposition; they think that about the only way to cut down expenses is to avoid being fined for overspeeding, and consequently they slow down every time they see anything that looks like a bluecoat, and imagine that by so doing they are reducing operating expenses."

"Does your dream include always keeping a bluecoat in sight?" tauntingly interrupted the downstairs skeptic.

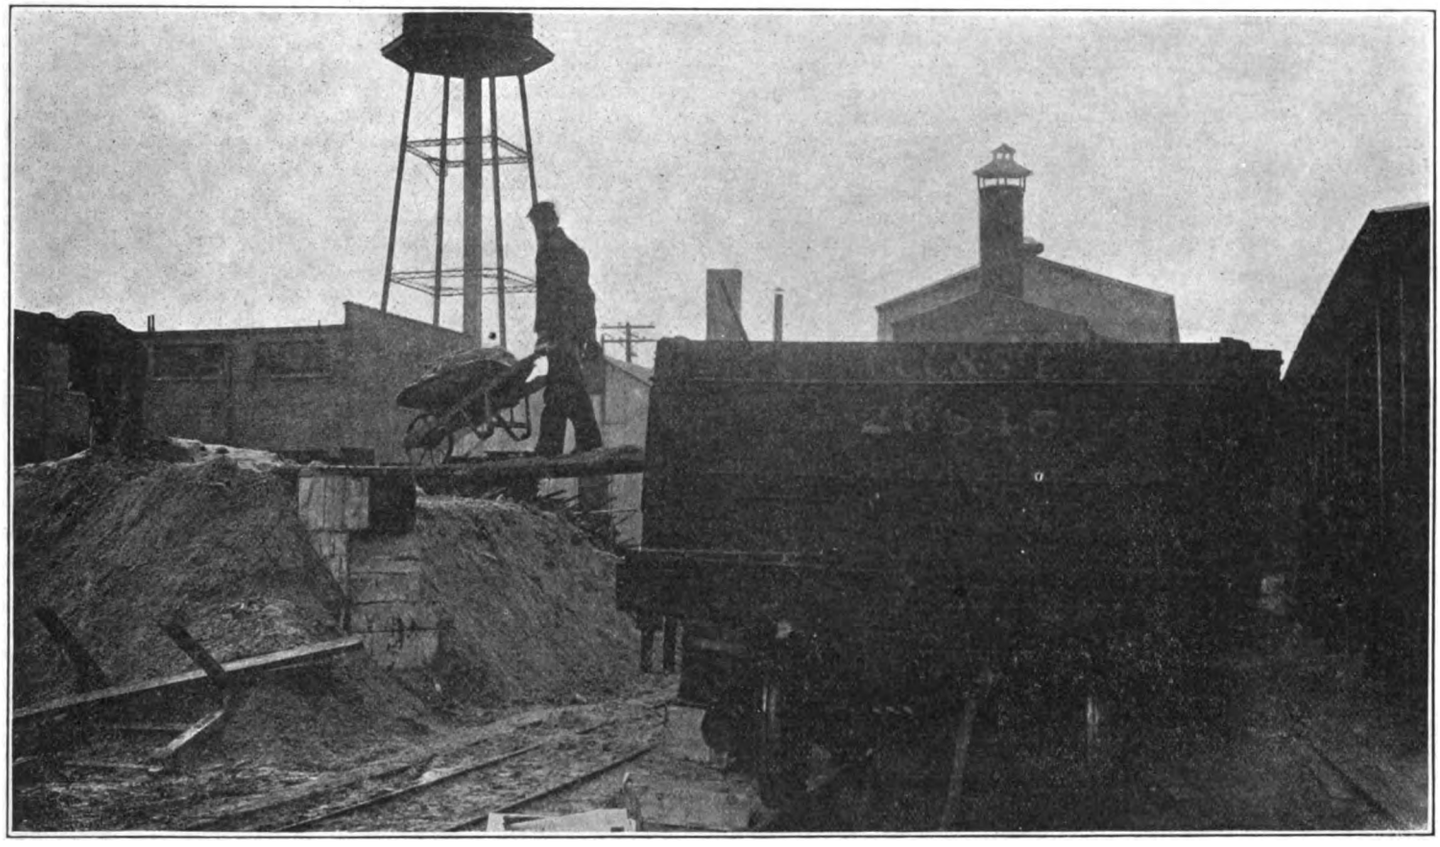
"Oh, you go to!" retorted the assistant designer. "I'm in earnest; and if you know anything at all you know that about the quickest way to gain the attention of any individual is through the medium of his pocket book. When the price of gasolene or other liquid fuel reaches the stage where the operating costs when the motor is run spasmodically at high speed are greater than the fines, it seems to me not unlikely that the victim of this speed fever will himself call for the antidote.

"What will be the medicine? Well, perhaps there 'ain't none.' That disease probably is incurable. The desire to pass someone else never will be overcome in this country—it's too much a part of our lives. The cure will be worked on the car rather than on the individual, and it seems to me that will be in the form of check rain; a governor. Yes, a small hit and miss or throttle governor which will limit the supply of fuel will do a great deal toward lessening the costs of motoring, and it is not at all improbable that the use of such a device will be just as common with the pleasure cars a few years hence as is the case with the motor trucks to-day, and with every bit as much success."

"Sounds reasonable! But 'come again.' You said you had two economical streaks."

"Yes, but the other is more in the nature of a personal opinion—a pet hobby, so to speak—and—— Oh, well; I'll give it to you, anyway. It is a fact that an internal combustion motor, to be at all economical—or, in other words, to be thermally efficient enough to compete with the steam engine—must compress the charge before firing. It is likewise true that the degree to which the compression is carried has a very decided effect on the thermal efficiency of the machine, but, of course, this is not without limitations. Now, the limit to which the compression of gasolene vapor can be carried before there is a falling off in the efficiency has not yet been reached, for the very simple reason that if the compression is carried much beyond the standard 70 pounds per square inch, considerable loss of power is caused by premature igni-

Digitized by Google



tion. During a series of tests made by the United States government to determine the degree to which compression could be effectively carried using gasolene as a fuel, the fuel was fed through the medium of a carburetter and in order to prevent pre-ignition water was also injected into the cylinder in quantities varying from one-half that of the gasolene until equal with the gasolene. The compression was carried to 130 pounds with no sign of preignition. The thermal efficiency of the motor remained the same throughout these tests as problem resolves itself into the one of elimination of the fuel from the cylinder until the position of the piston precludes the chance of pre-ignition working any negative effect."

"That means liquid injection of the fuel?"

"Yes, and why not?" Among the many other functions which tend to determine the effective power which can be taken from a gasolene engine of a given size, none stands out more prominently than does the cylinder volume. Now, consider the the air in the first case must be supplied. Isn't it perfectly reasonable, then, to expect an increase in power when the fuel is injected as a liquid?"

"Oh, I know that liquid injection isn't new and that the drawback is in the production of a homogeneous mixture, but I fully believe that by properly designing the fuel injection valve and the combustion chamber the mixture can be made to equal the mixture supplied by the present carburetter. The system need not necessarily be more complicated than at present; for a

FACTORY SCENE THAT DOES NOT CONVEY ITS OWN SUGGESTION

Not waste but molding sand being unloaded at R. C. H. plant in Detroit.

it was with the lower compression; the power was neither increased nor decreased, as was also true with the rate of fuel consumption, and this despite the fact that the available cylinder volume was limited and the effective temperatures lowered by the introduction of the water. Doesn't it seem reasonable that with the compression increased without recourse to the injection of water or by any other means which would tend to to have a negative effect a rather large field for the increase of the thermal efficiency of the gasolene motor is thrown open?

"As for the means of preventing pre-ignition, to me it seems rather a simple matter. It is certain that if no explosive mixture exists in the cylinder before the time for regular ignition there will be no early explosion, no pre-ignition, so that the charge which fills this volume; where gasolene is the fuel there are 7.3 volumes of air to each volume of vaporized fuel, which proportion forms theoretically the correct mixture. If the air and the gasolene have been mixed on the outside of the cylinder, one-eighth of the cylinder volume is occurpied with the gasolene vapor. If the fuel is not injected with the air, or, in other words, if the fuel is injected as a liquid, the total cylinder volume is occupied by the air before the introduction of the fuel. It stands to reason that the amount of air in the second case exceeds the first amount by approximately 12 per cent., and as a consequence when the fuel finally is injected at the completion of the compression stroke in order to produce perfect combustion of the mixture an excess of 12 per cent. over the amount taken in with four-cylinder motor but two pumps are necessary, both double-acting and driven by suitable cams; or possibly one single-acting pump would suffice if worked in conjunction with a suitable distributing valve. One thing is certain, however, and that is that the proportion of gasolene vapor mixed with the air could be made constant without the shadow of a doubt simply by varying the stroke of the fuel injection pump as the speed changes, or, in other words, as the throttle is opened. And when we get a car or a truck of that sort, believe me! we will not be using gasolene or carburetters.

"Wow!" was the cruel retort to this final flourish of earnestness. But the exclamation was followed by the well-timed disappearance of the doubter from downstairs.

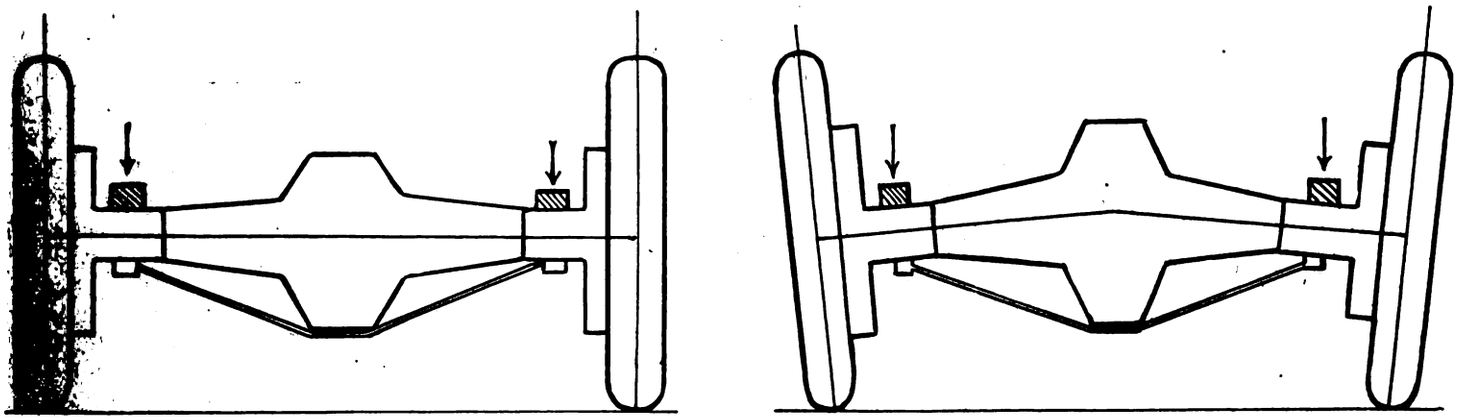
THE ARCHED REAR AXLE IN THEORY AND PRACTICE

Dissection of the Principle of the Arch That Tends to Disprove the Accepted Belief That an Arched Axle May Be Stronger Than a Straight One—Why the Straight Axle, Weight for Weight, May Sustain the Same Loads.



According to Ridpath's encyclopedia, an arch is defined as "a structure composed of separate wedge-shaped pieces arranged on a curved line so as to retain their position by mutual pressure." Church, who is inclined to go more deeply into the mechanics of the principle, describes an arch as "a structure spanning an opening or a gap, depending, for stability, upon the resistance to compression of its blocks, or vousoirs, the material of which is not suitable for sustaining a tensile strain." Though the mechanics of arches in their multitudinous forms is more or less involved. and their comprehensive study requires the equal of an excellent technical education, the underlying principle upon which all arches depend is comparatively simple and is well within the pale of conception of the average man.

The analogy between the arch and the automobile is this: Some manufacturers, though the number is very small, use arched rear axles in preference to the orthodox and very much more popular straight type. Probably because of the extended use of arches in engineering work and the exceptional amount of strength obtainable for a given quantity of material, provided proper percautions are taken in designing, the arched rear axle generally has come to be recognized as being of greater strength, weight for weight, than the straight axle. And there is a possiblity that it really may be slightly the stronger of the two, though there is no data available which will prove the point beyond cavil.

On the other hand, it certainly cannot be any weaker than the straight axle, the weight and quality of material and the class of workmanship being the same in both cases. But if the theory of the arch be studied carefully, without the necessity for recourse to figures or formulæ or abstruse reasoning, it must become apparent that it surely is opposed to the idea that an arched axle can be any stronger than a straight axle.

To cite Ridpath's definition, for instance, which is about as good a definition as can be obtained: "Separate wedge-shaped pieces arranged in a curved line . . . retain their position by mutual pressure." According to Newtons' third law of motion, there must always be an equal and contrary reaction to every action As to sustain weight is an action, it follows that there must be an equal, and contrary, reaction, which is to say that the force acting to sustain the weight must be equal to the force exerted by the weight itself. By reason of the structure of an arch, the weight of the arch itself and any additional weight which is placed on the arch places its separate pieces in compression. Consequently there must be an equal and contrary reaction to balance the action represented by the sustained weight, which could not otherwise be sustained. The reaction, in this case, is represented by the abutments of the arch. If the abutments were removed it follows that the arch would collapse for the simple reason that there would be nothing for the separate pieces to act against and consequently they could not be held in compression.

Substituting the arched rear axle for the arch, and applying the same reasoning, it becomes apparent: First, that as there is nothing to take the place of the abutments of the arch, the axle must collapse. Because it does not collapse proves that it does not follow the principle of the true arch, but relies for its strength not on the fact that the elements are placed in compression, in which case they might be expected to stand considerably more strain than they would in tension, but purely on the tensile strength of the materials. In the true arch, which, as has been pointed out, is composed of a number of separate pieces, no part ever is in tension; all parts constantly are in compression, which in itself is the reason for the arch, inasmuch as the resistance to compression of the materials of which arches are made, whether it be stone, or concrete, or steel, always is far greater than the tensile strength of the material.

DIAGRAMMATIC SKETCHES SHOWING THE CHARACTERISTICS OF STRAIGHT AND ARCHED AXLES

To fall back on the old example of the tied arched roof—merely for the reason that axles of either type generally are tied—it is plain that the only reason the arch remains in position is because of the tie rod. If the rod were removed the arch would collapse, there being nothing (figuratively speaking) against which its ends might abut. The strength of the arch, therefore, depends upon the tensile strength of the tie rod, and consequently the whole structure must be viewed as a beam under a bending strain. If the roof were flat, the tie rod would affect its ultimate strength to the same extent as it does the arched roof. In the former case the roof itself might be lighter, as its materials would stand a greater compressive strain than a tensile strain, though the tie rod would require to be made correspondingly stronger. In the second case the roof would require to be made stronger, in order to sustain the tensile strain of its own weight, but there would be no necessity

Digitized by Google

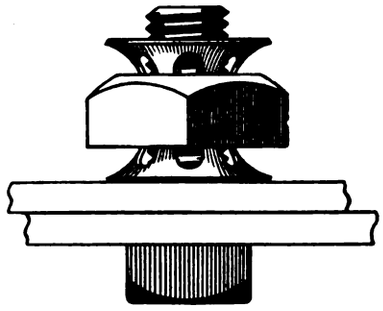
for the tie rod being as strong. In other words, to assume that the sustaining of a roof represents an action, the tie rod represents the contrary and equal reaction.

Substituting the axle for the roof this time, it becomes plain that the tie rod under the axle affects the ultimate strength of the axle, whether it be arched or straight, in the same way as the tie rod affects the strength of the roof, assuming, of course, that the straight axle and the arched axle are of the same weight and quality of materials. In either case, the strength of the axle depends upon the tensile strength of the materials and not upon their ability to resist compression.

In the accompanying diagrammatic sketches, both types of axle are shown and are of average construction. In order to assist understanding, however, the form of the arched axle is considerably exaggerated, the actual amount of arch seldom being more than three degrees and more generally being approximately two degrees; in the illustration the angle approximates six degrees.

If both axles were loaded until a bending strain was caused, an interesting phenomenon, tending to prove conclusively that the principle of the arch actually is absent, would result. In the case of the arched axle, the wheels would spread at the bottom, owing to the reduction in the camber of the axle. As the arch depends for stability upon the fact that its "legs," if the ends may be so styled, cannot spread, it becomes plain that the arched axle is not an arch at all, but that it depends for strength on the tensile strength of the material of which it is constructed. In the case of the straight axle, the bending strain would cause the wheels to incline inward at the top. It is obvious, therefore, that a consideration of the functions of the tie rod does not upset the conclusion that the arched axle is an arch in name only.

Though it may perhaps be inferred that the frictional resistance between the tires and road possibly might serve as the abutments of the "arch" and thus permit the material in the axle to be placed in compressive strain rather than in tension, an example suffices to disclose the absurdity of the idea. Even if it be assumed that the frictional resistance is sufficient there are times when one rear wheel drops into a hole, in which case the frictional resistance not only is lost but if the tire encounters an inwardly sloping side of the hole the actual effect is even worse than it would be if the frictional resistance really were depended upon.



By way of still further indicating the misapprehension which may exist let it be assumed that each spring perch of an axle having an arch of three degrees supports, say, 600 pounds, and that the axle itself weighs 300 pounds. By reason of the distribution of the weight on the axle only part of it acts directly on the apex of the arch, and this part may be placed roughly at 500 pounds; 100 pounds represents the weight of the axle acting directly on the apex and 400 pounds represents the weight of the car. By means of well-known formulæ, the strain acting to force the wheels apart at the bottom may be computed to be approximately 50,000 pounds. Against this pressure there is only the frictional resistance between the tires and the road, which, allowing 1,500 pounds as the total weight on the tires and a coefficient of friction of as low as 0.5, amounts to some 750 pounds. To repeat Newton's third law of motion, namely, "every action must have an equal and contrary reaction," the absurdity of considering the frictional resistance between the tires and the road as sufficient to hold the wheels together becomes plain.

As to what may be the effect on the stability of the car and the ability of slightly "dished" wheels which the arched axle permits to resist fracture, there is a wide diversity of opinion, though it appears on the whole that the advantages and disadvantages of each system very nearly balance. The arched axle, of course, necessitates that there be some means of flexibly connecting the drive shafts with the differential mechanism, but this in itself is comparatively easy of solution, and as the angularity between the shafts and the differential pinions is very slight in any case the amount of power used up in friction in the coupling is so small as to be practically negligible.

There is one point on which the arched axle scores, however, and that is on appearance. It is conceded by not a few that a slight outward inclination of the tops of the wheels makes for a more pleasing effect. Obviously, there are an equal number who abhor "dished" wheels. After a car with a straight rear axle has been run for a couple of seasons, however, there is the likelihood that the axle may have sagged slightly, in which case the tops of the wheels will incline inward, and even if the inclination is not sufficient to cause the tires to come in contact with some other part of the body, the effect will be unsightly at least. With the arched axle, on the other hand, considerable sagging might take place before the wheels would incline inward to any appreciable extent.

Simple Means for Keeping Nuts Tight.

One of those little things that are simple, inexpensive and yet valuable is the lock nut—a device that has been made in a great variety of forms, all more or less effective. Perhaps the simplest of the number, however, is the new Worth wedge washer, manufactured by the Steel Specialties Co., of Boston, in styles and sizes suitable for all sizes of bolts and all threads. It is simply a steel washer stamped into a conical form, with its inner edge toothed. As the illustration shows, the washer is applied under the nut with the teeth up, and the nut screwed down upon it, the wedging action forcing the teeth into the thread of the bolt and holding the nut securely. If a few threads of the bolt project above the nut a second lock can be applied, with the teeth toward the nut, and locked by forcing down the outer edge with a piece of pipe and a hammer, or by screwing a second nut down on it until the washer "turns inside out," to use the maker's expression.

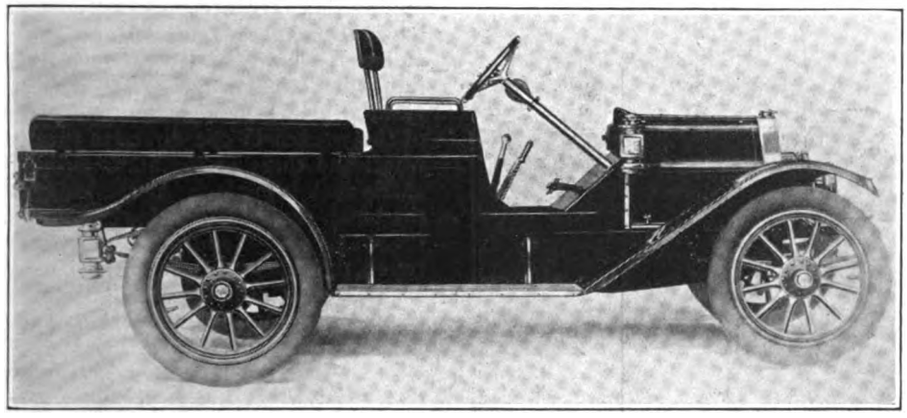
WORTH WEDGE WASHERS

An Extortion Scheme That Failed.

Apropos of the many schemes that chauffeurs work to extort money from the unsophisticated, the following story is told by a New York motorist who is the posessor of two cars, and who suffered an accident last week in which the car he was driving broke its steering knuckle. There was nothing for him to do but to have the car towed home. He accordingly despatched his chauffeur to get the other car and a rope in order to perform the towing operation, and in the meantime, after fussing around with the interior of his car and getting thoroughly soiled, he sat down in the driver's seat to wait for the return of the other machine.

While he was sitting there an automobile with two young men of the chauffeur type riding in it came up. They sized up the situation at once and saw that he was in need of help. One of them hopped out of the car and walking over to the owner, who was sitting on the front seat, said: "All right, young fellow, we got a telephone message from your boss giving us the number and we are here to tow you to the garage."

The owner of the car concealed his amusement and merely said: "I don't move from this spot no matter what telephone message you got." The other fellow blustered a little and insisted that he had a message ordering him to look out for a car broken down of the same number of this machine and wound up by saying he'd bring suit against the man for the expense of going out to look him up if the car were not towed in by him.



Finally the owner declared himself and the two beat a hasty retreat. If they had been able to get away with it they probably would have extorted a good bit of money from the automobilist for towing his car uptown.

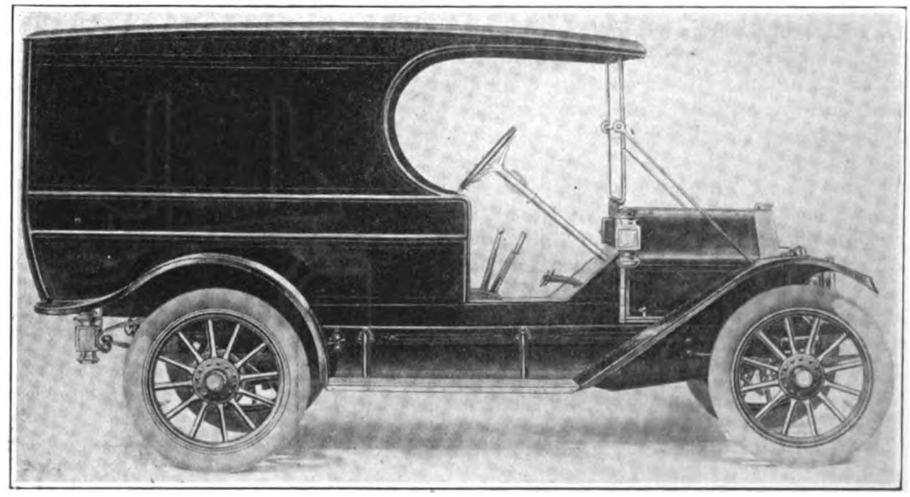
OVERLAND ADDS TWO NEW WAGONS

Both of 800 Pounds Capacity and Employ Sliding Gears and Pneumatic Tires—Center Control a Feature.

That there is a field, and a big one, too, for the light motor delivery wagon daily is being demonstrated with greater conclusiveness. "Big Business," having delved deeply into the possibilities of the heavier commercial vehicles with gratifying results, slowly but surely is turning to the light motor wagon as a solution of terminal distribution problems embracing the necessity for rapid short hauls with comparatively light loads, and the results which have been achieved in a notable number of cases in which light motor delivery wagons have been used as auxiliaries to heavier trucks demonstrates the correctness of the theory. To the proprietors of smaller businesses, the light delivery wagon opens up a very much wider field, of course, a field that must of necessity remain barren to the merchant who relies on horsed equipment, with its limited radius of action and its inherent slowness. In appreciation of these facts, the Willys-Overland Co., Toledo, Ohio, just has placed on the market two new light delivery wagons which fit in between the truck and the package delivery car, and thus reach into the widening field heretofore occupied largely by horsed vehicles.



OVERLAND 800 POUNDS CAPACITY OPEN EXPRESS WAGON

Like the older commercial vehicles in the Overland line, the two new creations are essentially adaptations of the company's pleasure car chassis, and as such reveal many of the distinctive features which in the past have marked Overland cars.

The chassis of both the new wagons is exactly the same, the wheel-base being 106 inches. As its name suggests, model 59, which is styled a "Delivery Special," is a closed panel body wagon with an available loading space of 60 inches by 43 inches, the height from the floor to the top being 53 inches. The loading space on the "Express," which lists at $950, being $50 cheaper than the "Special," measures 67x42 inches; the height of the sides is 10 inches and the width of the side wings is 6 inches. In conformity with the nature of the loads which it is expected will be carried, and the capacity, which in each case is 800 pounds, both vehicles are equipped with 33x4-inch pneumatic tires mounted on quick detachable rims.

As regards the chassis, the motor is rated at 30 horsepower, the cylinders measuring 4x4½ inches bore and stroke, respectively. Cooling is by water, and for ignition Splitdorf equipment, consisting of a high tension magneto and an auxiliary battery system, is used. From the motor, power is transmitted to semi-floating rear axles through the intermediary of a cone clutch and three-speed selectively operated change gear mechanism. Like the newer Overland pleasure cars, the control levers, gear shift and emergency brake, are located in the center of the footboard, which position, it is deemed, permits of the greatest accessibility and facilitates control. The steering wheel is at the right, as usual. Two sets of brakes are provided, the service brakes being internal expanding and the emergency set external contracting, both operating on 10x2 inch drums on the rear wheels.

OVERLAND "DELIVERY SPECIAL" WHICH LISTS AT $1,000

REDUCING THE DANGERS OF GLASS

French Test of New Material That Appears to Hold Promise—Its Relation to Windshields and Windows.

While the great majority of accidents which now occur are caused directly or indirectly by carelessness and rarely ever can be attributed to faulty construction or the use of poor material, there is still at least one vulnerable point in modern car construction the elimination of which will lessen to a greater or less degree the dangers attendant upon such accidents. This vulnerable point is none other than the glass used in the windshield on nearly every car, and in the windows and doors of all the enclosed types of cars.

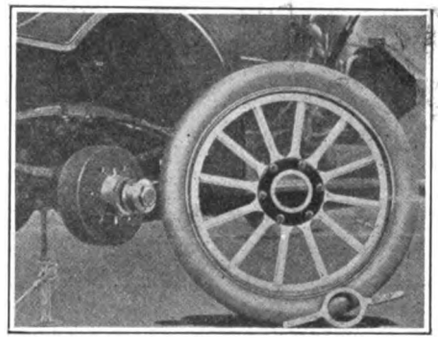
It is not unlikely that this source of danger will be present to a greater or less degree as long as motor cars are used, for at the present no substitute for glass which is really worthy of the name has come to light. True, celluloid has been tried, but it is expensive, easily scratched, very subject to damage by the elements and the various classes of grease used in motor propulsion, and, moreover, is highly inflammable. Until that very indefinite period when the composition of glass will be so altered as totally to eliminate, or at least greatly diminish its characteristic brittleness, it is quite evident that breakage will be of more or less common occurrence, so that at present the real problem involved in the protection of the motor car occupants from harm from this source of danger lies rather in the elimination of the flying splinters after the glass has been broken than in the elimination of chance of breakage.

To this end glass panels in which wire mesh of various sizes and composition are fused have been tried; however, there are several drawbacks which militate against the use of such panels. Unless the mesh

Digitized by Google

openings are rather small, the number and size of the splinters which fly are not greatly diminished, and if the openings are small the view of the road is obstructed. Then, too, if the mesh is made of any other metal than aluminum the reflection of the sunlight from the polished surface of the very numerous strands nearly blinds the driver; glass so armored is very likely to crack during temperature changes owing to the difference in the coefficients of expansion of the metallic substance and the glass, and, moreover, the cutting and fitting is very much more difficult than with ordinary glass.

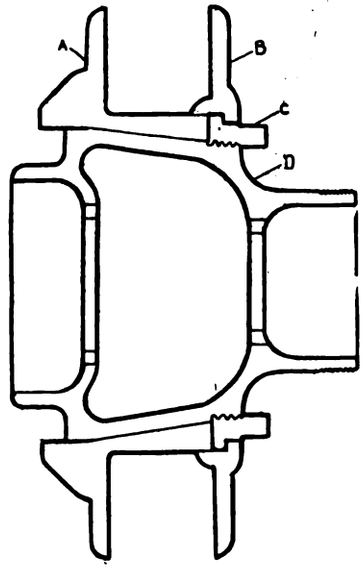
According to Omnia, a series of very interesting tests has been carried out in France to determine the value of a new product, "triplex glass," which is made up of a sheet of celluloid cemented under pressure between two pieces of glass.



The tests were conducted to determine the relative quantity and distance to which they were projected, of the splinters from a sheet of plain glass, wire mesh armored glass and "triplex glass" when sheets of the same were subjected to shocks or blows of the same intensity. Each sheet tested was 20 centimeters square and was supported vertically in a wooden frame; each sheet was struck my a metallic ball weighing 900 grammes, which was fastened to the end of a flexible cord, the other end of which was made fast to the ceiling at a distance of 3.75 meters above the center of the pane. The ball traveled in a curvilinear path, the length of which was the same in each case. The blows were therefore constant. Tests were made on ten sheets each of the plain, wire mesh and "triplex" glass. The average of the results shows that whereas with the plain glass 80 per cent. of the total surface was broken into splinters which were projected, with the wire mesh glass 30 per cent. of the glass was splintered and projected, while with "triplex" the splinterage amounted to but 2 per cent. A correspondingly great divergance in the distances over which the splinters of the different sheets traveled is shown in the average of the results; with the plain glass the splinters traveled 5.7 meters, with the wire mesh glass 5 meters, while with "triplex" the distance to which the splinters were projected was but 20 centimeters. The thickness of the glass was five millimeters for the plain, and seven and six millimeters, respectively, for the wire mesh and the "triplex."

The glass is made with the celluloid supported between plate glass for use in windshields, and between ordinary window glass for use in the doors and windows of the enclosed car. The manipulation is very much more easy than is the manipulation of the wire mesh armored glass. To cut it, it is simply necessary to scratch in the ordinary manner save that a scratch is made on either side. The glass is then cracked along the double scratch and bent first one way and then the other for a few times until the celluloid parts.

SIMPLIFYING DEMOUNTABLE WHEELS



Chicago Firm Makes a Stride in That Direction—Renders Unnecessary Even to Remove Hub Cap.

As a solution of the problem of providing a quick and easy method of replacing a deflated tire with an inflated one, Ellsworth & Cross, 332 South LaSalle street, Chicago, Ill., have developed and placed on the market a new type of demountable wheel the characteristics of which are such that it should go far toward increasing the popularity of such devices. In perfecting

E. C. DEMOUNTABLE WHEEL

the wheel it has been the object of the manufacturers to eliminate as many removable parts as possible and so successful have they been that the wheel itself is the only part which can be removed. Further-

E. C. WHEEL HUB CONSTRUCTION

more, it can be removed without the necessity for disturbing either the hub cap, the axles, or the brake drums.

Barring the inherent simplicity of the mechanism, probably its principal advantage is that the demountable joint is well above the road, at an easy working height, where it is not liable to accidental injury and where it is comparatively free from the insidious action of the elements; the joint itself is machined to insure that the wheel runs absolutely true. Another of the advantageous features of the wheel is that it is self-pulling under all conditions. In order to obtain this feature, the wheel itself has an inner flange (A), as indicated in the accompanying illustration, and an outer flange (B), which are independent of the wheel hub (C), but which fit the latter through a taper joint. Housed between the two wheel flanges is the locking and pulling ring (D), which extends a short distance through the outer flange, thus providing a sleeve with two opposite holes into which pins on the special wrench provided with the equipment fit. Three turns of the wrench in one direction remove the wheel and three in the other direction securely lock it in place. At the inside end of the taper, there are two lugs which engage the wheel flange and make movement between the taper and the wheel impossible.

In order to insure against the wheel coming loose on the road, the locking and pulling ring is provided with ratchet teeth around its periphery into which two dogs drop as the ring is screwed up into place. These dogs, which are not shown in the picture, are housed in bosses in the outer flange, and when the wheel is to be removed are pried up and hooked out of engagement temporarily. That there may be no danger of their being left out of engagement when a new wheel is put on, however, the wrench is so shaped that it automatically releases them, making it impossible to tighten up a new wheel without its being securely locked.

Skull Crushed by Motor Truck Chain.

What probably is the first accident of the sort with motor trucks occurred on Friday last, 29th ult., on Lenox avenue, near 133d street, New York City, resulting in the death of Lemuel Reese, a seven-year-old boy. According to the testimony of eyewitnesses, the boy was roller skating and was trying to get hold of a passing motor truck belonging to the National Sugar Refining Co. A lurch of the truck brought his left arm into contact with the heavy driving chain, and the boy's body was dragged into contact with the sprocket, where his skull was crushed.

Automobile Instruction for Vienna Police.

Heeding the call for better informed policemen, the city of Vienna has decreed that every member of the police department must go through a three-weeks course in practical automobile instruction, in order to be at least fairly conversant with the chief characteristics and the handling of motor cars in cases of emergency. The training course is divided into two parts; the first week is spent in the Technical High School in listening to theoretical instruction in the construction of automobiles; and the second and third weeks in the Fiat factory.

"WATERED MIXTURES" TO PROMOTE EASY OPERATION

Old Subject is Revived and Discussed and Point Given to It in an Address to Agricultural Engineers — Government's Experiments With Gasolene and Alcohol Fuels Recalled and Success With Heavy Distillates Emphasized.

Long years ago, when the development of the gas engine was still in its infancy and pertinent information regarding the properties of explosive mixtures of gas and air was decidedly lacking, pioneers in the experimental field concluded that the internal combustion motor should be patterned more or less after its prototype, the steam engine. To this end the valve gearing and the crank gearing assumed a decided steam engine pattern, and it was only after repeated experiments had proved the good points, and pointed out the bad ones, that the internal combustion motor design became more or less distinctive. It is not surprising that the experimenters directed no mean part of their efforts toward the control of gases after the introduction of the ignition flame in unsuccessful endeavor to limit the initial pressures, which are naturally high, and to produce a working pressure behind the piston which would be constant throughout the stroke, for it was thought that by this means the thermal efficiency of the motor could be made more nearly to approach that of the steam engine.

Naturally the lines of experiment were many and divergent. Everything from stinting the mixture and specially designing the combustion chamber to the introduction of steam and hot water with the explosive mixture were tried with little success. But this does not imply that the initial pressures were not reduced. Reduction there was and plenty of it, but with this reduction came a decided drop in efficiency, especially where water was introduced. This falling off in the thermal efficiency scarcely can be wondered at when it is considered that the engines which were used for the experiments fired the charge at asmospheric pressures, and the flame propagation, which naturally is slow in gases not under pressure, was further retarded by the contamination of the mixture with water.

Experiment along the line of the injection of "watered mixtures" lay practically dormant for a long term of years after these first failures, which were conducted by Lenoir, a Frenchman. Not until the internal combustion motor was brought to its present state of perfection were any experiments along the line which proved of any practical value recorded. Not the least interesting of these later experiments are those conducted by the technologic branch of the United States Geological Survey to determine the relative values of denatured alcohol and gasolene as fuel for combustion motors. The conclusions drawn from this rather exhaustive series of tests are that although the introduction of water tends to decrease the power available from a motor if the degree of compression before firing is not altered, the practice has much to recommend its adoption in that a much smoother running motor is produced; much of the jar consequent on the rapid expansion of the gases after ignition is eliminated and "steam engine" smoothness of operation is the natural result.

When, however, the water is introduced it is possible to increase the degree of compression without causing pre-ignition. The tests show that under the circumstances the compression can be increased to 140 pounds to the square inch, about double that adhered to in the design of gasolene motors. With the compression so increased all of the losses consequent on the absorption of heat by the water and the retardation of the speed of flame propagation are compensated for by the advantages of the higher degree to which the gas is compressed, and the power available is equal to that available from the motor with normal compression working without water. A general smoothness of operation, however, obtains.

Not long since, however, it was noted that the introduction of water in suitable quantities into the combustion chamber of a motor using as fuel any of the lower grades of petroleum, such as kerosene and distillate, had besides all of the effects which obtain with its use in a gasolene motor three others—the promotion of complete combustion, elimination of the smoke of the exhaust and reduction in the formation of carbon deposit. The exact reason or the reasons for these effects, all of which are good effects, is at present a matter of conjecture pure and simple, but some interesting sidelights were thrown on the subject by James A. King, of Charles City, Iowa, in a paper, "Low Gravity Fuels for Internal Combustion Tractors," read at the recent annual meeting of the American Society of Agricultural Engineers. Speaking of the chemical action to which Mr. King considers the results to be due, he said:

"Into the problem of burning the heavier oils there enters a chemical peculiarity inherent in the more complex hydrocarbons. They are subject to what is known as 'cracking.' At a given temperature any one of them with a molecular formula above a certain degree will break down into a simpler compound.

"This temperature of cracking is below the temperature of ignition, and takes place without producing ignition. In this process of cracking a given molecule will break down into one or more molecules of the same series. Except in the naphthene or ethylene series this cracking results in the setting free of carbon.

"Since the paraffin series predominates in most of the petroleum fields of the United States, I shall confine this discussion to that series. The following equation will tend to illustrate what takes place when an oil cracks:

(1) $C_n H_m$ + Heat = 2 $C_r H_s$ + C.

"As stated before, the temperature at which cracking takes place is lower than that of ignition. Consequently, this freed carbon immediately assumes a molecular state. This molecular carbon, unless prevented from doing so, is deposited as amorphous carbon and it is well known that amorphous carbon is decidedly inactive under normal conditions.

"The above illustrated action will explain why it is that the ordinary gasolene engines will not successfully burn these lower gravity fuels for any considerable time without a serious carbonization of the working parts of the cylinder and piston.

"In view of the facts set forth above and which are to follow, it is rather difficult to understand the credence given to the statement made after the close of the 1911 Winnipeg motor contest, that any engine will successfully burn kerosene and distillate simply by making a slight change in the carburetter by which the ingoing charge is heated so as to hasten the process of vaporization. They will burn it, yes. But to burn it successfully they must do it with the greatest possible economy and efficiency. To do it with economy an engine must get maximum combustion with minimum expense or intereference with the working of the engine. To do it with efficiency the engine must burn this fuel in such a way as to realize a maximum percentage of the heat of combustion as useful work. In either case the engine must continue to do this throughout its normal life, not for a few hours or days. And it cannot do this without providing some means of uniting this freed carbon with oxygen under conditions which shall render the resulting liberated heat available as work.

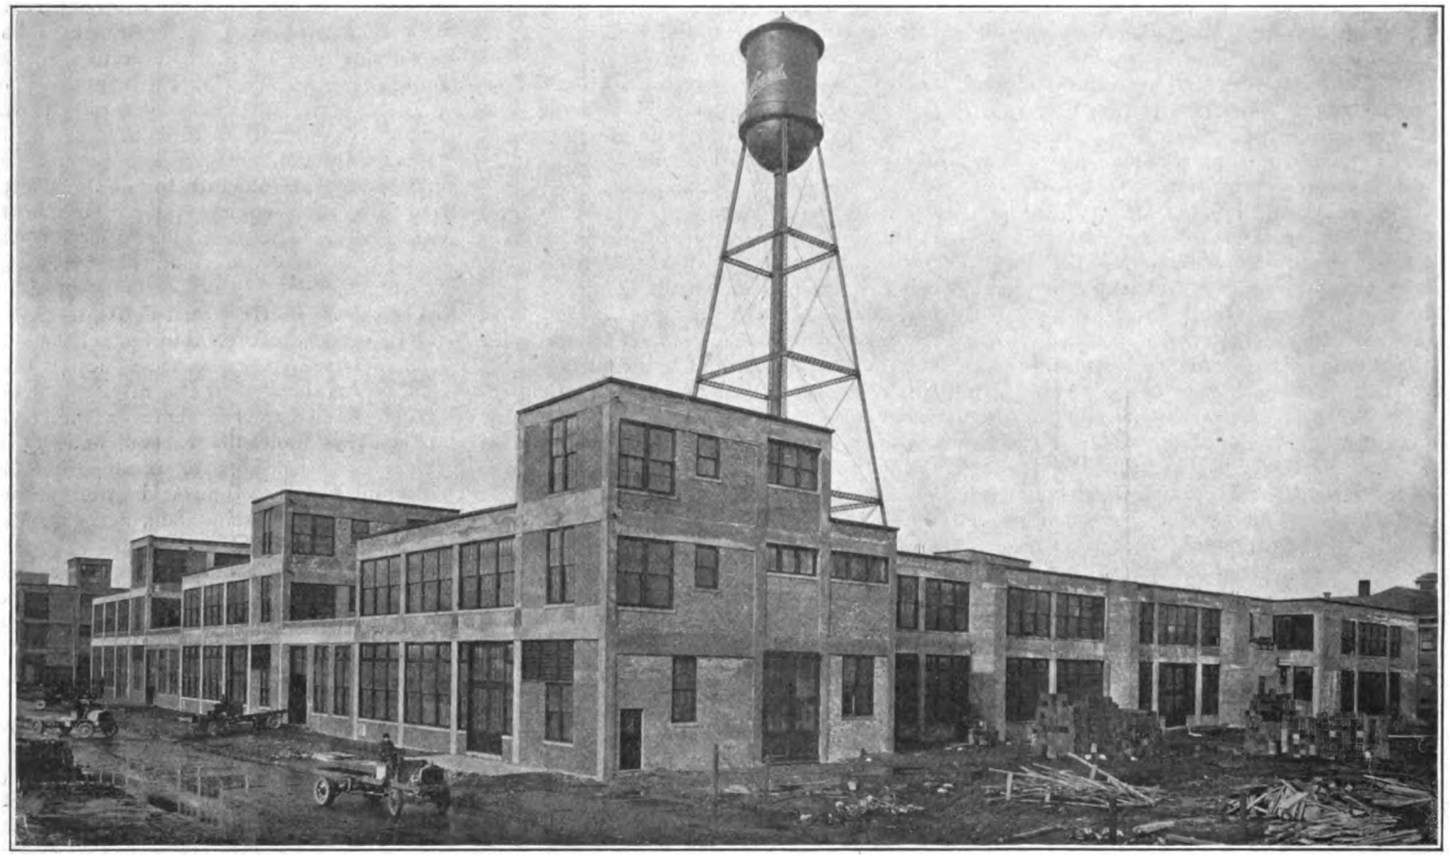
"It was noted that when a charge of

Digitized by Google

petroleum testing between 55 degrees and 38 degrees Baume was ignited in the presence of a small quantity of water vapor, the combustion is much more rapid and complete than when the water is absent. Recognizing this fact, some manufacturers of kerosene burning engines provide some system for spraying a small quantity of water into the cylinder coincident with the spraying of the fuel.

"The following chemical equations seem to explain the reactions which take place from the time the charge is drawn into the cylinder until combustion has ceased:

(1) $C_{16}H_{34}$ + Heat = 2 C_7H_{16} + C.
(2) C_7H_{16} + 7 O_2 = 7 CO_2 + 16 H.
(3) 2 H_2O + Heat = 4 H + 2 O.
(4) C + O_2 = CO_2.
(5) 4 H + O_2 = 2 H_2O.



"As has been stated, reaction (1) takes place before ignition and is the process known as cracking. When the electric spark has ignited the charge a reaction such as (2) takes place. The heat generated by this is sufficient to run the temperature inside the cylinder of an engine working on normal load up to about 3,000 degrees Fahrenheit. This temperature is sufficient to dissociate water and so the hydrogen of (2) does not unite with oxygen when released by the carbon in favor of oxygen, but remains free. At the same time reaction (3) takes place because of the high temperature generated by (2).

"Now, free carbon and normal oxygen of the atmosphere unite only at very high temperatures, higher than those produced inside the cylinder of a working engine. But nascent oxygen is much more active, uniting at lower temperatures. So reaction (4) is coincident with (3). The nascent oxygen liberated by the dissociation of water in (3) unites immediately with the free carbon. Reaction (4) would liberate heat in compensation for that absorbed in (3), so that the pressure here would be maintained.

"Due to the law of temperatures of gases under compression, as the piston moves outward the temperature of the gases within the cylinder decreases because of this expansion. At some point in the outward stroke the temperature falls below that of the dissociation of water. It is then, and not until then, that reaction (5) takes place. In this reaction the oxygen is that of the air and the hydrogen is that which was set free in reactions (2) and (3)."

Further on in his paper Mr. King states that the introduction of water with the fuel, besides tending to eliminate carbon deposit, "increases the efficiency of the engine and also of the fuel by its effect on interior temperatures. These more complex fuels always run an engine hotter than do the simpler fuels when pulling the same load. This difference in temperature seems to exist especially at the compression end of the cylinder. If an engine's cooling system is designed to let the engine work at the highest temperature consistent with efficiency when working on gasolene, it will, when burning the heavier fuels, soon become so hot that the piston will bind and even stick in the compression end of the cylinder if no water spray is used. But the use of water overcomes this difficulty. The dissociation of the water, as shown in reaction (2), absorbs a great amount of heat and so reduces the total temperature of the cylinder chamber. Of course, this heat is again given up in reaction (5). But when (5) takes place the temperature has dropped below that point where it interferes with the proper working of the engine. So that the action of the water is not to decrease the total amount of heat units liberated during the entire process of combustion, but to so distribute it throughout the entire volume of the cylinder that the cooling system can properly control it. In fact, the presence of the water increases the total amount of heat units liberated, because it makes possible reaction (4)."

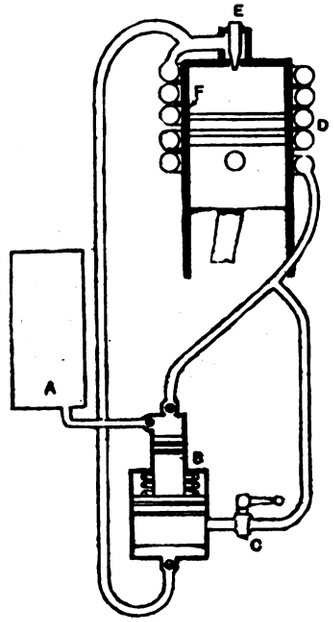
USES GASOLENE IN "WATER JACKET"

The "Boiled" Gasolene Then Automatically Injects Itself Into Cylinder—Other Features of a Remarkable Engine.



No matter what form the internal combustion engine of the future may take, and there have been any number of forms suggested, it is certain that its thermal efficiency will be very considerably higher than that of existing engines. At present it is not possible to utilize all the heat that is generated, and it never will be possible. Gradually, however, engineering practice is reducing this loss of heat and because of the concurrent increase of thermal efficiency, the ratio of power available to the weight of the machinery comes closer to its theoretical value. In respect to what eventually may be expected in the way of increased thermal efficiency, the Low engine, which is the invention of Archibald R. Low, of the British Low Accessories Co., is interesting not only because of several radical characteristics but because it indicates quite plainly the general tendency toward fuel injection as the most practical means of utilizing the greatest possible amount of heat generated.

The engine itself is not altogether unlike the now famous engine of Dr. Diesel, the thermal efficiency of which gradually has been brought up to the remarkable figure of 48 per cent., with a corresponding mechanical efficiency, in some cases as high as 35 per cent. of the heat value of the fuel. Like the Diesel, the Low engine shows notable thermal efficiency, exceptionally high mechanical efficiency resulting as a matter of course. It is said that an experimental two-cylinder V type engine having a bore and stroke of 51 mm. and 102 mm., respectively (2 x 4 inches) actually developed between 16 and 18 horsepower on the brake. By common proportion, allowing a fair percentage for friction, it becomes plain that an ordinary four-cylinder engine with a bore and stroke of say, 4 x 5 inches, if its thermal efficiency corresponded to that of the Low engine, would develop in the neighborhood of 100 horsepower.

In principle the Low engine is quite similar to the Diesel engine in that only pure air is compressed. The similarity is carried still further in that fuel in the form of pure gasolene vapor is injected into the combustion space after the compression of the air is complete, though the similarity ends there. Far from doing away with sources of ignition other than that of the heat of compression, ignition in the Low engine is effected by a spark coil and plug and is continued during the whole of the working stroke, the theory being to effect as complete combustion as possible.

The most radical feature of the engine and the one on which it depends for operation and its remarkable efficiency, is that the ordinary water jacket is replaced by copper tubes which contain gasolene instead of water. In starting the engine an ordinary type of carburetter is used and the engine is run until a certain pre-determined heat is obtained, when the carburetter is disconnected and the other cycle of operations is taken up. What actually happens is that the gasolene in the outer tubes literally is boiled into vapor (gasolene boils at temperatures varying from 125 to 200 degrees, according to its specific gravity), and under its own pressure is injected into the combustion space through a valve automatically operated by the piston. The explosive mixture so obtained then is fired by means of a spark plug and coil in the orthodox manner.

One of the peculiar features of the gasolene vapor valve is that by reason of its

LOW ENGINE IN DIAGRAM

method of actuation, which at present is one of the dark secrets of the inventor, it opens very abruptly but closes comparatively slowly, the result being that vapor is injected for a considerable portion of the working stroke. The effect obtained is that the piston receives a steady thrust rather than an abrupt and intermittent series of blows, and consequently the torque diagram of the crankshaft shows appreciably flattened "peaks." The burned gases are exhausted in the usual way by means of a third valve.

Preignition is impossible, of course, for the simple reason that only pure air is compressed. This permits of exceptionally high compression pressures being used and is responsible in a measure for the unusual thermal efficiency of the engine. Perhaps the part of the engine which shows the greatest ingenuity on the part of the inventor is involved in the method of maintaining the supply of gasolene in the jackets. This is effected by means of a pump of the Worthington type which operates by the pressure of the gasolene vapor itself to inject fresh gasolene into the heating jackets after the manner of locomotive pumps which maintain the supply of water in the boiler by variations in the steam pressure. The pump, which is shown in the accompanying sketch, is of the differential piston type and operates against a spring. When the pressure in the gasolene vapor line drops, as when vapor is injected into the combustion space, the spring is permitted to expand and the lower end of the pump cylinder draws gasolene from the tank. As the pressure in the vapor line rises, due to the heat, the spring is compressed and the gasolene is injected into the jackets. The piston of the pump therefore "floats" while it reciprocates rapidly up and down, maintaining the supply of gasolene in the jackets.

In order to throttle the engine a valve controlling the supply of gasolene to the pump is provided, and this is interconnected with the air inlet valve in such a way that the cut-off regulates the supply of gasolene. Consequently, the quality of the explosive mixture remains constant at all times though the quantity may be reduced or increased according to the power requirements of the operator.

Bosch Puts Period to First Million.

When a manufacturer of anything larger than needles, pins, carpet tacks or toothpicks turns out his millionth article, he of right views it in the nature of an "event." And an event of that sort occurred in the history of the Bosch Magneto Co. when on March 15th the millionth Bosch magneto was turned out, the total representing the combined production of the factories here and abroad. It served to emphasize the expansion of the Bosch business since it was established in 1888 at a time when automobiles were dreams or curiosities and automobile magnetos unthought of.

The Proper Spreading of Split Pins.

One of the mistakes that very commonly is made, not only by amateurs but also by "professionals," is to spread the ends of split pins too far apart, so that if it becomes necessary to remove the pins considerable work is required in order to get the ends together. Pins that are likely to remain permanently in place may, of course, be spread to the limit; but those which are liable to be removed should be spread just enough to keep them from working back through the holes, which is all that is necessary.

Forcing Bolts in Place by Hammering.

A bolt that requires an excessive amount of hammering to get it into place is apt to be greatly weakened at the point where the head joins the shank, and an abnormal strain or shock may pull the head off. It is better to take just a trifle of metal off a bolt than to force it by means of heavy blows. A few strokes of a file generally will suffice.

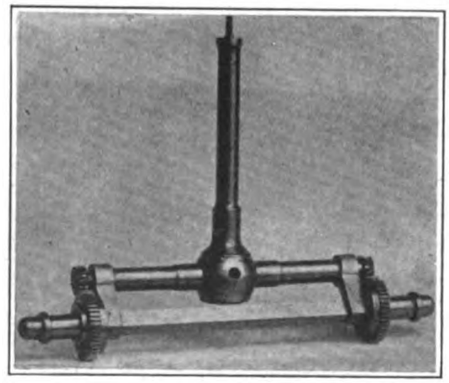
TRUCK WITH SUPPLEMENTARY AXLE

Purposes Which it Serves on the Piggins Vehicle—Cast Aluminum Front Construction and Other Features.

While the trucks and delivery wagons manufactured by the Piggins Motor Truck Co., of Racine, Wis., are in most respects of what may be termed standard design, embracing well-known and widely employed structural features, the final drive is of a type which, while not by any means new, is as yet unusual in an American machine.

On the rear axle, which is of solid steel of square section, is journaled a supplementary axle, the sole duty of which is to transmit power from the propeller shaft to the rear wheels; it carries no weight whatever. The supplementary axle is divided in the middle and carries the differential and bevel gear for the propeller shaft drive. On the outer ends of the axle shafts are spur pinions which mesh with internal gears bolted to the rear wheels. A casing encloses the gears, excluding dust and dirt, and, of course, facilitating lubrication. This system of final drive has its advantage, among others, in that it gives a gear reduction which permits the use of a comparatively small bevel gears for the propeller shaft drive, thus keeping the size and weight of the central gearing and housing down to very reasonable proportions, as the accompanying illustration of the Piggins rear axle system shows.



PIGGINS CHASSIS WHICH EMPLOYS EXTERNAL GEAR DRIVE

The motor of the three-ton truck, which is the machine illustrated, is of the T-head type, having four cylinders. Bore and stroke are 4½x5 inches, respectively, and the motor is rated at 40 horsepower. Lubrication is by splash, with a constant circulation of oil maintained by a pump. A dual ignition system is employed, with a Briggs low tension magneto and a battery of dry cells as the alternative source of current. Particular attention has been given to the radiator, in order to make it sufficiently strong for the severe service, the various parts being riveted together, in addition to the usual soldering, and the whole radiator strongly braced with bronze plates at the sides and on the bottom. These plates have cast integral with them the lugs for the holding-down bolts. The pump is of the gear type; the water capacity of the system is about 10 gallons.

Besides the rear axle and final drive already described, the transmission system includes a large leather-faced clutch, a three-speed Cotta change gear and a universal-jointed propeller shaft.

The entire front construction of the body, including the seat, toe-boards and floor-boards, is of cast aluminum, convenient openings being arranged, with suitable covers, giving access to the engine, which is under the seat and floor, and to the space under the seat. Four-inch channel steel is employed for the framing, with heavy steel gusset plates at the corners; all holes are drilled, not punched, and rivets are put in hot.

PIGGINS "DOUBLE AXLE" CONSTRUCTION

Piggins cars are built in five sizes, ranging from a half-ton delivery wagon to a five-ton truck. With the exception of the lightest machine, all embody practically the same mechanical features, differing chiefly in the matter of dimensions and weight. The smallest machine has the motor in front under a bonnet or hood.

With the exception of the engine, all bearings are ball bearings of the radial type; the engine bearings are of nickel babbitt. A dust pan under the truck protects the engine and other mechanism from dust and flying dirt. The wheel-base of the car is 120 inches; all wheels are 36 inches in diameter, and are fitted with solid rubber tires. There is a space of 11 feet in length and 40 inches wide back of the box seat that is available for loading purposes.

Equipment consists of acetylene headlight with gas tank, two oil side lights and oil tail light; top, with side curtains; three-ton jack, and set of tools. While a specialty is made of bodies of any type, unless otherwise ordered, trucks are furnished without bodies, with only the front seat in place.

Little Things That Affect Truck Engines.

On a motor truck, the engine of which is likely to be run much nearer its capacity than the engine of a pleasure car, it requires considerably less of inaccurate adjustment to cause trouble, in some cases, than in the lighter machines which have a much greater margin to come and go on, to use the common expression. For instance, a little loosening of the fan belt in combination with a slightly rich mixture, occurring in hot weather, may be quite sufficient to make the motor overheat every time a moderate grade is climbed. Flat fan belts are more liable to slip, as a rule, than those of V shape, unless made of ample width so that they stretch very slowly and have a large area of contact with the pulleys.

Sand Boxes or Chutes for Motor Trucks.

A box full of sand is a very handy adjunct for a heavy motor truck, especially when the route necessitates much travel over roads which are converted into mud holes by the early spring thaws. Probably two boxes provided with chutes so that the contents can be discharged in front of the traction wheels at such times as is necessary, and which can be operated by a pedal from the driver's seat, would save the driver considerable time and not a little bother.

Glycerine That Preserves Radiators.

Glycerine regularly is used during the winter months to lower the freezing point of the cooling solution. But there is no reason why it should not be used during warm weather as well, not to prevent freezing, of course, but to eliminate the formation of scale in the radiator. One-half pint to each five gallons of water will suffice. The practice is in quite general use so far as steam boilers are concerned, especially on marine boilers.

"CHAUFFEUR FACTORIES" AND THEIR METHODS

"Big Money and Easy Work," the Lure That Has Led to Much Disappointment and Has Overstocked the Market With "Graduates"—High-Sounding Catch-Phrases That Are Employed and How They Match With Stern Reality.

"Be a chauffeur and earn big money!"

It is many years since more or less startling advertisements conveying, more or less specifically, the idea expressed in this exhortation commenced appearing in daily papers and magazines, and it is safe to believe that they will continue to appear just as long as the population of the earth includes considerable numbers of that sort of persons who are born every minute or those who are incapable of earning more than a pittance, but who possess unfathomable yearnings for occupations which will yield generous returns for a small investment of labor.

While the ball was started rolling, in all probalibity, by concerns wanting canvassers and who advertised for men to "do a gentleman's work and reap a harvest," or "look at Mr. Jones, who earned $43.79 the first day; you can do the same," it has been kept moving at a lively rate by "institutions of learning" of all sorts, from those who guarantee to train the voice by mail to the "secret process" fraternity. But it is doubtful if any particular part of the educational field ever was so assiduously and so successfully cultivated as the automobile school idea. Naturally, the aeroplane movement has stirred up considerable activity in educational circles of a sort, and. to judge from some of the advertisements, anyone can now be taught to fly by mail "by the use of our wonderful models" and a series of printed lessons; some of the automobile schools have modestly tacked aviation to their curriculums, as is quite appropriate. But as yet the freest flowing fountain of knowledge is that from which motor car lore springs, and there is no sign of diminution of the stream. "Learn to fly and win fame and tortune" has an alluring sound, but "Be a chauffeur and earn big money" sounds a lot more practical, for everyone knows that aeroplanes are comparatively scarce, while automobiles as yet are as the sands of the sea by comparison.

Let it be said that there are schools of instruction, many of which give courses by mail, that are absolutely honest, that give excellent instruction, that promise no more than they can perform, that do not indulge in bombastic advertising, and that make charges that are not of the bargain order, but warrant the expenditure of the time and trouble required to teach that which is claimed to be taught. Such institutions are in a class by themselves, and are by no means to be confounded with those that flaunt the lure of "big money and a gentleman's job."

Not the least interesting phase of the automobile school business of the "cheap and quick" class is the shrewdness displayed in the struggle to enroll students. Of course, the first step is the advertisement; and, as a great deal depends upon first impressions, the advertising is cleverly calculated to stir to its depths the possible student's yearning for a "profession" that will enable him to earn vastly increased wages while doing what is held up to him as "easy, pleasant work." Big, black letters fairly shout the most enticing (and inaccurate) statements. "Big money is being made by everyone in the automobile business;" "Constant big demand for chauffeurs and repair men such as we teach you to be;" "Be a chauffeur and draw $200 a month;" "Be an auto expert for $15;" "Would you rather work hard for $12 a week, or take life easy, travel, and earn $30 a week;" "Ours is the only gasolene engine university that graduates its students from a real automobile factory;" "The most lucrative trade on earth is auto engineering;" "Get a highly paid position at once;" "Generous salary for easy, agreeable, outdoor work;" "Our graduates always in demand;" "Why be a slave when we can teach you to make money like a gentleman." And so on, until the credulous reader's brain doubtless whirls with visions of a life of ease and plenty. That's the way it looks in the advertisements. But there is another aspect of the matter which perhaps is best indicated by a little story that has the merit of being quite true.

A certain merchant who uses in his business a big gasolene truck required a chauffeur for the machine and advertised for one. Unfortunately he had neglected to read the "auto university" literature, and he therefore didn't know that the automobile business was the best trade in the world; otherwise he doubtless would not have advertised that he was willing to pay the right man $18 per week. And it was hardly to be expected that anyone seeking for "easy, pleasant work" would expect to find it on a truck, to say nothing of such mattters as traveling, short hours and so on. But nevertheless when the merchant reached his office the morning after the appearance of his modest little ad. he had literally to push his way through a crowd of "auto college graduates," diploma holders, mail-instructed experts and a sprinkling of just plain chauffeurs, all of whom displayed a lamentable ignorance of the fact (?) that innumerable easy, well-paid positions were waiting for them. Not quite relishing the task of personally interviewing so many applicants, the merchant opened the door enough to thrust his head through, and explained to the crowd that the job was a hard one, the hours were long, the chauffeur would have to help with the loading and unloading, that the truck was a "brute" and needed a good deal of attention, and that it must be ready for service on time every morning, barring serious trouble. "And," concluded he, "any of you fellows who don't like the prospect had better not waste any more time here." He waited for a moment. One rather flashy-looking individual unostentatiously poked the elevator "down" button and departed—alone. To shorten the yarn, let it be said that the merchant interviewed man after man until he found one who appeared to be a good fit for the job, and engaged him on the spot. But the interviewing process brought out some queer tales. The first man admitted was one of those who had learned by experience. He had no diploma, but he had his hard luck tale and his own opinions.

"These here auto schools," he complained, "is turnin' out so d——d many ginks that can't do nothin' better'n answer a couple o' questions on a paper that they ain't enough jobs to go 'round. They work so cheap that prices is all knocked out an' a good man can't hit a decent job once in a dog's age."

The first man's story was, in essence, the story of all the men who had not taken automobile school courses. But those who had been so "educated" had a wail all of their own, and they all agreed in the substance of it. The theme was that there were so many uneducated men looking for jobs—men who never had had any automobile school work, but had picked up a little knowledge here and there and could just about drive a car as long as it was in good shape—that there was little chance for a real "automobile university" engineer. And then the "engineer" would dig into his breast pocket and produce a diploma with a big red seal—a document that bore evidence of having been so produced many times. When asked to tell of his qualifications for the job the graduate would explain how the boss instructor had given him six road lessons of half an hour each, when he watched the other fellows "shooting trouble" and occasionally took a hand

Digitized by Google

himself. Then he would launch forth on a pitifully elementary explanation of how he would proceed in case the motor stopped suddenly on the road. It always was the same. And he was thoroughly competent to drive and care for any kind of a car—of course. But he had not had a regular job as chauffeur, or else he had been only a few days in a position and left because—well, because he didn't like it. And so forth and so on.

This is not a fanciful case, neither is it unique. The cities are crowded with men looking for jobs as chauffeurs, repair men and what not. It is true that there always is room for a first-class man—a man better than the average of his trade—but even such a man as this does not find it an easy matter to locate himself once he gets out of work, for no one can tell merely by talking to a man how good he is, and he has to prove his worth before he can occupy his share of the "plenty of room" that proverbially exists "at the top." Truly, the song that the "auto colleges" sing is a siren song, and many there be that heed it, and while some have had a little experience and know what to expect, and some use their brains, others believe nearly everything they see in print and are undone.

The story of the man who wanted the chauffer—which also is the story of a great many other men who have wanted chauffeurs—goes to show that the average man of little or no education is prone to enumerate his chickens previous to incubation. He believes he can obtain the key to a well-paid "profession" by spending a little money and giving up a little time to study, when he will be in a position to take a leisurely look around, pick out a job that combines the greatest number of points that are advantageous according to his lights, and settle down to enjoy himself and draw his salary. Those are exactly the ideas that a thoughtless, green young fellow would be filled with after a perusal of a batch of advertisements of a certain class of so-called automobile schools, and they are exactly the ideas that they are intended to be filled with. To be sure, these curious hallucinations do not last long; but before they are dispelled the would-be "engineer" has received his "education"—and has paid for it.

Everyone has learned to read sensational advertisements with a good deal of—well, toleration. Reasonable allowance is made for the enthusiasm of the advertisers, and not too much is expected. But even after making the usual deductions some of these technical education advertisements leave so much room for dazzling dreams that it is only natural for many young fellows to make the mistake of imagining that they are going to obtain a great deal for a ridiculously small outlay—something that is directly opposed to all the laws of nature, of physics and of social economy.

Time was when the mere idea of "being a chauffeur and pulling down a fat salary" was enough to keep "classes constantly forming" at the various seats of learning; but multiplication of the founts of wisdom had the natural effect of causing the principals to add other inducements. Naturally the promise of a job after graduation came first, but the obvious impossibility of making such a binding agreement has given way to the more conservative, safer and almost as effective stipulation that graduates will be assisted in obtaining positions, backed by assertions as to the money that is waiting to be picked up in the automobile business, the scarcity of good men and the constant demand for graduates of "our institution" and the like. Road lessons which involve the use of an automobile are indispensable, and here enters a spice of low comedy, for some of the antiquated wrecks rudely aroused from what should have been their last sleep are absolutely side-splitting. Who has not seen an ancient and honorable one-lunger wheezing and rattling along under the burden of a "class" of anywhere from four to ten "students" who stuck on wherever they could get a foothold and watched one of their number learning to drive while the "road instructor" divided his time between showing his pupils how to manipulate a control system long obsolete, and keeping the poor old rattle-trap running, Who has not seen one of these cars stalled, with the "professor," perspiring and profane, trying to get it started once more on its uncertain way, while the grinning "pupils" made a ring around the show and offered facetious advice? These are the occasions when the teacher ceases teaching and the students are at rest.

Of course, there is as much difference between automobile schools and their methods and results as there is between men. A really good automobile school has the same general characteristics as any other school. It will state in explicit terms just what may be expected in the way of education and what the terms are. The fees asked are the fees that are paid—there is none of the elasticity that permits a fee to shrink to an extent that is in exact proportion to the prospective student's reluctance to take the school's course. Examinations are real examinations, diplomas are withheld until earned, and the dropping of students because of their inability to grasp the subjects presented to them is not unheard of. The cars used for road instruction are real cars of current models—cars that will give students an insight into the working of a machine of to-day, rather than of a hoary relic of the past. The instructors really are able men, having thorough technical educations. And so on. From this high standard the schools grade downward till the bottom of the ladder is reached, and at the lowest rung will be found some such thing as a fourth-class repair shop that is called a school so that a few boys can be induced to "enroll" and do rough work on cars in return for "tuition," the idea being, of course, to get help for nothing.

The whole situation is summed up in the familiar saying: "You can't get something for nothing." It is impossible to acquire knowledge without labor—both physical and mental labor, so far as the subject in question is concerned. Competent instructors will not give their services for a pittance, and they naturally are averse to having their reputations as teachers smirched by turning out pupils who are a discredit to them. And as for anything so absolutely ridiculous as making a gasolene motor expert of any man who comes along in the course of eight or ten weeks, or eight or ten months, for that matter, it is only necessary to go to an experienced man who has followed the gasolene motor since its early years, and ask him how long it took him to learn "all about the internal combustion motor." If he is inclined to be a little communicative he will repuly, gravely, "Sonny, I have been working on gasolene motors nearly all my life, and I find that the longer I am at it the more I have to learn."

Easy Way to Replace Valve Springs.

When replacing valve springs a lifter is not necessery, as there is a much quicker and easier method. Insert the spring in a large vise with each end resting against a jaw and compress the spring by screwing up the jaws, leaving enough of the spring above the top of the jaws for a string or wire to pass through the center of said spring. When compressed so that the coils of the spring are touching, tie it in two places with string. After it is tied it is taken from the vise and put in place on the engine and the washer or pin or whatever is used can be inserted and the strings cut. There are those who advocate using copper wire instead of string, but the wire is apt to catch in the spring and affects its proper operation, while string will work itself out in short time if it does not come out readily when cut, and will not affect its working in any way.

Little Things That Choke Carburetters.

Just because there is a "separator" in the gasolene line it is not always safe to conclude that there is no possibility of getting the spray nozzle choked or the line blocked. Sometimes, particularly in a new machine, a great deal of fine matter can get through and cause trouble at the carburetter, and it is by no means a rare thing for a little scrap of waste or rag, or a shaving, or a pellet of solder to interfere with the flow of gasolene sufficiently to starve the motor.

"Prying Up" Renders Valve Stems Useless.

Not a few valve stems are bent, and the whole valve thus made useless, by carlessness in prying up the spring in order to remove the pin so as to release the spring when the valve is to be removed. While it is not always possible to have proper valve removing tools when they are needed, it is entirely possible to be careful and not bend the stems, which are rather soft and easily distorted.

CASTOR OIL THAT FAILS AS AN ENGINE LUBRICANT

Explanation of the Reason for Its Value as a Lubricant for Rotating-Cylinder Engines That Makes Plain the Impracticability of Its Employment for Automobile Engines—Analyses Conducted by a Painstaking Chemist and the Results Obtained.

Whatever may be the value of castor oil in other fields it has little practical value for internal combustion engines of the fixed cylinder type such as commonly are used in motor cars. At least, such is the opinion of a British chemist, rendered after exhaustive tests to determine the physical properties of the oil as compared with straight mineral oils, and its behavior in use.

Though little if any attention has been directed toward the possibilities of castor oil as a lubricant in America, foreign motorists have for some time debated the advisability of "changing over" to it. As a matter of fact, not a few of them already have done so, and although the results obtained have not been such as to set the world afire they have not been altogether unsatisfactory, and the very diversity of opinions which prevail emphasizes the timeliness of the tests. It is doubtful if the tendency toward the more general use of castor oil as a lubricant can have been fostered by hopes of "reduced cost of running." At the present market price, castor oil such as is regularly supplied by a noted firm of New York druggists especially for lubricating fine machinery lists at 11 cents a pound in five-gallon lots, which figures out at the rate of approximately 90 cents a gallon. Comparing this figure with the average cost of the best quality mineral oils, which is 75 cents a gallon, the difference becomes apparent. It is more probable that the apparently increasing popularity of castor oil abroad is due to the success which has attended its use in aeronautical engines of the rotating cylinder type. However, such engines operate under vastly different conditions than do fixed cylinder engines, all of which is expounded by a writer in the Autocar, who states that though castor oil undoubtedly is an "excellent lubricant" it must be "used with discretion" in an internal combustion engine.

The conclusions of the writer are based in part on the results of tests made at the factory of Messrs. Clement-Talbot, in which a number of mineral oils, and incidentally castor oil, were used under the same conditions, a car being run in each case 1,000 miles. After each test the engine was taken down to ascertain its condition with regard to efficiency of lubrication and the amount of carbon deposit which had accumulated, the report of the engineer who examined the engine after the test with castor oil being as follows:

"'After this test, all four pistons looked very much alike; each one had a thick hard, shiny and fairly smooth deposit on top and very little on the sides. All the rings were quite free and well lubricated. The cylinder heads had a thin, hard deposit all over, and the valve caps had more deposit than with any other oil. The valve pockets also contained an exceptional amount of carbon.'"

In commenting on the report and leading up to his conclusions on the value of castor oil, the writer says: "This short report gives the impression that castor oil leaves perhaps an exceptional amount of 'carbon deposit' as compared with other oils, and this is emphasized by the actual weights of the deposit, which are given herewith. The cylinders were very carefully withdrawn, and a special slotted tray was fitted around the connecting rods under each piston in turn. The whole of the deposit was carefully scraped into the tray and removed with a camel's hair brush into a receptacle to be weighed. The deposit from each piston was weighed separately, but in the following figures the total weight on the four pistons is given for the castor oil (C)—which was the very finest quality obtainable; for pure mineral oils (A, B and F), prepared from the highest class crude, but differing chiefly in viscosity, and for mineral oils (H, G), prepared from an inferior crude. The relative viscosities are placed against each:

	Relative viscosities at 140° F.	Total weight of deposit on pistons. Grammes.
A. Pure mineral oil.....	1.0	5.12
B. Pure mineral oil.....	1.5	6.57
F. Pure mineral oil.....	2.3	9.54
H. Inferior mineral oil..	1.1	8.32
G. Inferior mineral oil...	2.2	13.55
C. Castor oil.....	4.4	14.08

"From this it will be seen that the 'carbon deposit' is greater with castor oil than with a low grade heavy-bodied mineral oil as G.

"In my opinion castor oil can be only used in fixed cylinders with impunity for short distances, and then with repeated cleanings between runs, but on rotary engines of the Gnome type cleaning is almost unnecessary. The reason is that one cannot consistently use castor oil over and over again, for the fact is indisputable that it has a far greater tendency than mineral oils to absorb oxygen, and so gradually to increase in body and finally to gum. When once it commences to gum the carbonization becomes more rapid, because the thickened and pitch-like oil acts as an insulating covering on the top of the pistons and of the cylinder, and cannot get away with sufficient rapidity to avoid decomposition and baking to a coke. Therefore if castor oil is to be used on the ordinary stationary cylinder type of engine, it is necessary to wash out the crank chamber and to replace with fresh oil at frequent intervals.

"On a rotary engine such as the Gnome this cleaning is unnecessary, because there is a continuous stream of fresh castor oil brought into the crank chambers and then thrown by centrifugal force past the pistons and through the cylinder into the exhaust. Thus the stream of oil never has sufficient time to oxidize fully, gum or decompose. This action of centrifugal force accounts for the large consumption of oil on the rotary engine, and also for the fact that the pistons and cylinders keep comparatively clean. It is noticeable in this connection that the castor oil from the exhaust of a rotary engine is pale yellow in color, and shows practically no sign of change from its original condition, whereas castor oil which has run some few hundred miles in the crank chamber of ordinary non-rotary type engine is almost black, and considerably more viscous than new oil. It will also be found to have undergone considerable chemical change; its specific gravity will have increased, and its iodine value decreased. This combination indicates that oxidation or gumming has occurred.

"In thus criticising the use of castor oil I do not wish it to be inferred that it is not an excellent lubricant. What I wish to suggest is that in the case of an internal combustion engine it must be used with discretion. A point in favor of castor oil is the fact that it maintains its viscosity in a remarkable manner at high temperatures, and that at those high temperatures it has a peculiar creeping or capillary action which enables it to spread uniformly over the whole of the metallic surfaces, whereas under the same conditions a similarly bodied mineral oil would be unevenly distributed in patches. Another point is that the specific heat of castor oil is considerably higher than that of a pure mineral oil. This is in its favor, insomuch that it shows castor oil to be a better heat remover than a mineral oil.

"Motorists and aviators have from time to time informed me that they are using castor oil, but have apparently been under

Digitized by Google

some misapprehension. I find that they have been using a brand of prepared oil under the impression that it is a specially refined castor oil, or that it is a blend of castor oil with a pure hydrocarbon oil, in which blend the office of the hydrocarbon oil is supposed by them to be one of protecting the particles of castor oil from oxidation. This ingenious idea, however, would not appeal to a physicist or chemist.

"Some time ago, being myself under the impression that this particular brand of oil, on account of its name, had some kind of relationship to castor oil, I purchased samples A, B and C from the ordinary sources and analyzed them. I found them one and all to be simply refined mineral oils, free from any traces of castor oil. Below I give some of the tests of these brands, as compared with castor oil:

	A.	B.	C.	Cold drawn castor oil.
Viscosity at 70° F.	1,080	1,530	2,340	3,810
Ditto at 140° F.	129	147	198	370
Ditto at 200° F.	55	55	64	88
Flash point, open	405° F.	371° F.*	475° F.	480° F.
Ditto, closed	396° F.	364° F.	460° F.	460° F.
Saponifiable matter	0.24%	0.27%	0.28%	99.74%
Unsaponifiable matter	99.76%	99.73%	99.72%	0.26%
Iodine values	17	11.4	20.4	83

*This extremely low figure for flash point caused me to repeat the test three times, and the resluts in each case were found to be the same.

"For the benefit of those readers who do not understand the term 'saponifiable,' I would say briefly that the property of being saponifiable is the one which essentially separates mineral oils from fatty oils, i. e., from oils of animal and vegetable origin. An oil to resist saponification must resist the action of an alkali such as soda or potash. Fatty oils do not resist such action, but are split up, yielding glycerin and a soap. Mineral oils, on the other hand, might for all practical purposes be called 'unsaponifiable,' and are generally only affected by the action of alkalis to the extent of 1 per cent. or less.

"The iodine value of an oil may generally be taken as an indication of the extent of its 'unsaturation,' or perhaps one might say more simply that it is an indication of the amount of oxygen which that oil is capable of absorbing. It may be taken as a universal rule, to which there is only one exception (which is not castor oil), that commercial fatty oils have iodine values between 25 and 205, while mineral oils vary from 4 to 21, according to their state of purity and their origin. The more pure and highly refined a mineral oil is the less will be its iodine value.

"In conclusion, I would call attention to the essential difference which exists between mineral oils and castor oil in the chemical tests, i. e., saponification and iodine values as distinct from physical tests. for, although it is possible to manufacture mineral oils having the same viscosity and specific gravity as castor oil at given temperatures, yet it is quite impossible to imitate saponification and iodine values."

OFFENSIVENESS OF EXHAUST GASES

Analysis Proves That With Carburetters Properly Adjusted it is Inconsequential—Two Samples "Dissected."

Looking at the matter from an ordinary, everyday point of view, there is not much reason for becoming too well acquainted with the exhaust gases from a gasolene motor; in fact, a distance usually is desirable. Taking the scientific view, however, entirely changes the aspect of the case, and when a chemist goes to extremes and picks apart, bit by bit, a sample of exhaust gas, measures, weighs and labels each particle and gives the character and pedigree of each, the thing becomes interesting.

In the first place, the chemist looks upon gasolene with a suspicious eye, and upon examination finds that it is by no means the simple stuff it appears to be. It really is made up of a complex assortment of hydrocarbons containing varying quantities of hydrogen and carbon. Vaporize this mixture, mix it thoroughly with just the right quantity of air and burn it and the result is carbon dioxide and water; the latter quite naturally takes the form of steam. If there is not sufficient air—that is, if the mixture is too rich—carbon monoxide is produced, and while this poisonous gas is odorless, it is accompanied by decomposed but unburned hydrocarbons which have a fearful smell.

As for the atmosphere which forms such an important part of the explosive mixture, only about one-fifth of it is of any real use, so far as combustion is concerned. This fifth is oxygen, and the other four-fifths or thereabouts are nitrogen, which is chiefly remarkable, in this connection, for its negative qualities. It does not burn; it does not assist the other gases in burning; it has no odor; it does not change in any way during the process of combustion—in fact, it is an inert dilutant, and it issues from the exhaust pipe in the same form and volume a swhen it entered the carburetter.

All this by way of leading up to the actual chemical analysis, which looks so dryly scientific that it seems as though something really ought to be said to liven it up a little. A six-cylinder gasolene motor was carefully adjusted as to its carburetter and run at its normal speed until it was warmed up to its regular working temperature. Then two samples of the gases were taken, sample A at a point 28 inches from the exhaust port of the motor and sample B 35 inches from the port. After the chemist finished his work all that remained of the gases were the following tables:

Sample	A	B
Carbonic acid gas	8.70	8.15
Oxygen	2.75	3.50
Carbon monoxide	.30	.95
Hydrocarbons	6.55	5.70
Nitrogen	81.70	81.70
Total	100.00	100.00

In looking over these analyses the first thing the chemist has to do is to explain the fact that he seems to have failed to find any water, though certainly water, in chemical combination, went into the cylinders. The explanation is that the water really forms a very insignificant part of the mixture, and though in the form of steam it made quite a considerable showing, when cooled it probably was deposited on the walls of the vessels containing the gas as an imperceptible dampness. The nitrogen content is the same in both samples, forming a very large proportion of the whole.

The differences in the gases shown by the figures resulting from the analysis of the two samples permit some interesting deductions. For instance, it is noticeable that in sample A, which was the one taken nearer the motor, there are unburned hydrocarbons to the amount of 6.55 per cent., while in the sample taken further along the pipe the quantity dwindles to 5.70 per cent. The explanation evidently is that the gases still were burning as they passed through the pipe, so that less unburned hydrocarbon remained when B was taken than when A was taken. The theory of continued combustion would suggest that sample B would show an increase in the amount of carbon dioxide—which is another name for carbonic acid gas—in proportion to the difference in the volume of unburned hydrocarbons in the two samples. But such is not the case and the chemist again has to explain. His theory is that deposits of hot carbon in the pipes, or particles of hot carbon in suspension in the gas, would have a tendency to reduce the carbon dioxide to carbon monoxide.

There would seem to be no real excuse for the increase of oxygen shown in sample B over sample A, and the chemist has to fall back on something that his books do not tell him. The idea is that there probably existed some small leak which permitted a little extra oxygen to be mingled with the sample. There is no chemical explanation.

The samples show less than 7 per cent. of gases that can be classed as evil-smelling, and though this is not entirely perfect combustion it is very good indeed. If no motor ever did worse there never would be any fuss about the motor car as an olfactory nuisance.

1,001,950. Carburetter. Thomas J. Hart, Jewettville, N. Y., assignor to Sherwood Manufacturing Company, Buffalo, N. Y., a Corporation of New York. Filed Nov. 26, 1909. Serial No. 529,854.

1. A carburetter comprising a mixing tube provided with a plurality of spiral partitions which divide the same into a plurality of spiral longitudinal mixing passages, and means for supplying air and gasoline to said passages.

1,003,949. Signal Lamp for Vehicles. Almor M. Puckett, San Antonio, Tex. Original application filed Dec. 1, 1910, Serial No. 595,146. Divided and this application filed May 25, 1911. Serial No. 629,429.

A lamp comprising a body, a reflector arranged therein, a sign holding box having an open side disposed opposite said reflector, and light conducting tubes extending from the body at right angles to each other and arranged in the same horizontal plane, said tubes being disposed below said box and one of them arranged opposite said reflector.

1,003,963. Motor Vehicle. Russell Huff. Detroit, Mich., assignor, by mesne assignments, to Packard Motor Car Company, Detroit, Mich., a Corporation of Michigan. Original application filed June 27, 1908, Serial No. 440,699. Divided and this application filed Oct. 12, 1910. Serial No. 586,749.

1. In a device of the class described, the combination with a crank case having a laterally extending arm, of a magneto shaft mounted in bearings in said arm, a member of a universal coupling on the end of said shaft, a flange on said member, and a pulley secured to said flange.

2. In a device of the class described, the combination with the crank case having a laterally extending arm, of a magneto shaft mounted in bearings on said arm, an armature shaft for the magneto in line with said shaft, a universal coupling joining the ends of said shafts, a flange on the member of the universal coupling on the magneto shaft, and a pulley having its web bolted to said flange.

1,004,582. Tire for Vehicle Wheels. William D. McNaull, Toledo, Ohio. Filed Jan. 28, 1911. Serial No. 605,143.

1. In a device of the described character, a demountable rim comprising a metal ring having a deep peripheral circumferential channel, tire engaging members upon the opposite margins of the channel and providing opposed circumferential grooves, combined with a flexible tread member having beaded margins which fit into said circumferential grooves, and an inner pneumatic tube the inflation of which forces the beaded margins of the tread member into engagement with said circumferential grooves, the transverse horizontal width of the recess formed by the channel of the rim and its tire engaging members being greater than the width of the tread member when distended, and of such depth as to contain the tread member and, when deflated, the pneumatic tube

1,004,598. Support for Speedometer Gearing. Albert L. Soper, Cleveland, Ohio, assignor to Warner Instrument Company, Beloit, Wis., a Corporation of Illinois. Filed May 5, 1910. Serial No. 559,557.

1. In combination with a vehicle wheel and steering knuckle having a vertical portion supporting the wheel and a pair of steering arms, a gear carried by the wheel, means for transmitting movement from said gear to a measuring device comprising a transmitting gear which meshes with said gear, means for holding the transmitting gear in proper position relative to the gear which it engages comprising a member in addition to the steering arms projecting from the vertical portion of the knuckle, and a supporting device for said transmitting gear clamped to the extreme end of said member.

1,004,626. Tire for Vehicles. Michael J. Cantor and Ernest Siegel, New York, N. Y. Filed Apr. 7, 1911. Serial No. 619,497.

1. A vehicle wheel comprising a felly provided with dove-tailed recesses, an outer concentric rim also provided with dovetailed recesses registering with those of the felly, double dove-tailed resilient members each adapted to fit into an opposed pair of such recesses and retaining members each also adapted to fit in the same pair of recesses to limit the relative movement of the felly and the outer rim.

1,004,628. Headlight or Other Light-Projector. William Churchill, Corning, N. Y., assignor to Corning Glass Works, Corning, N. Y. Filed Sept. 14, 1910. Serial No. 582,082.

1. In a headlight or other light projector, the combination with a casing and a lamp of a lens of the Fresnel type and an outwardly flaring and reflecting hood, the inner edge of which meets and surrounds the operative face of the lens, the angle of the reflecting surface of the hood being such that the rays projected from the source of light through the miters of the lens, and caused to diverge away from the axis of the beam, shall be caught and reflected by said surface so that they shall proceed in an approximately parallel beam, thus reinforcing the strength of the beam projected by the lens, substantially as set forth.

1,004,639. Pneumatic Tire Rim. Sylvester Cline Force, San Francisco, Cal. Filed Jan. 6, 1910. Serial No. 536,643.

In a pneumatic tire holding rim, a wheel, a felly therefor, a rim around said felly, said rim having one portion thereof beveled and having a tire holding flange and another flange in contact with the felly, a removable flanged ring adapted to fit the beveled portion of the previously mentioned rim and having a tire holding flange and a flange in contact with said felly, bolts passing through the flanges in contact with the felly, flanged nuts to secure the removable ring and beveled rim in place on the felly, and lugs carried by the removable ring to project over the flanged nuts, substantially as described

1,004,655. Wheel. Simon P. Johnson, Westpoint, Neb. Filed May 27, 1911. Serial No. 926,846.

1. In a wheel, the combination with a hub, a wheel rim comprising a pair of laterally spaced annular members, and spokes connecting the members of said rim with each other and with said hub, of a supplemental wheel rim that is transversely severed and detachably seated on the members of the first noted wheel rim and spanning the opening therebetween, means for anchoring one of the severed ends of said supplemental wheel rim, and an anchored draw bolt secured to said supplemental wheel rim in the vicinity of its other severed end, for drawing said supplemental wheel rim on the first noted wheel rim, substantially as described.

1,004,658. Spring Tire. Joseph M. Keller, Philadelphia, Pa. Filed Nov, 21, 1910. Serial No. 593,317.

1. A tire tube, comprising two strips of spring metal having oppositely disposed convolutions crossing each other, said strips spaced apart, each strip proportionately widest at regular intervals, proportionately narrowest at equal distances between the widest portions, the outer edges of said strips having a compound curvature, rings located at opposite sides of the tube, and elastic connecting devices inside of the tube projecting through the tube and rings, and securing devices against the outer faces of said rings holding said elastic devices, substantially as described.

A non-skid tire that grips the road

The strong, sturdy appearance of the Federal Rugged Tread (non-skid) Tire is evidence of its rugged construction—its exceptional durability—its ability to withstand excessive strains, stress and wear.

The heavy, expanding base knobs grip the road with wonderful tenacity and give the greatest traction under all road conditions. The knobs are shaped so they offer a myriad of skid-resisting angles the full width of the tread at the point of road contact. Users of tires appreciate the advantages afforded by this *real* non-skid tire.

Ask any Federal tire dealer to show you the Rugged Tread—no argument will be necessary — its features will be obvious on examination.

We will be pleased to send further information on request.

Rugged Tread

Round Tread

FEDERAL TIRES

A quality tire of "Extra Service"

The Federal Round Tread Tire is a tire that gives the limit in mileage and motorists look upon it as the tire of *"Extra Service."* Its extreme durability is due to the fact that it is made of the highest grade materials by the most skilled workmen. It is a tire of unusual quality—the *extra* mileage is built into it.

Federal Tires are made to fit all standard rims and are procurable through leading dealers and auto supply houses everywhere—an interesting tire book mailed on request.

Service

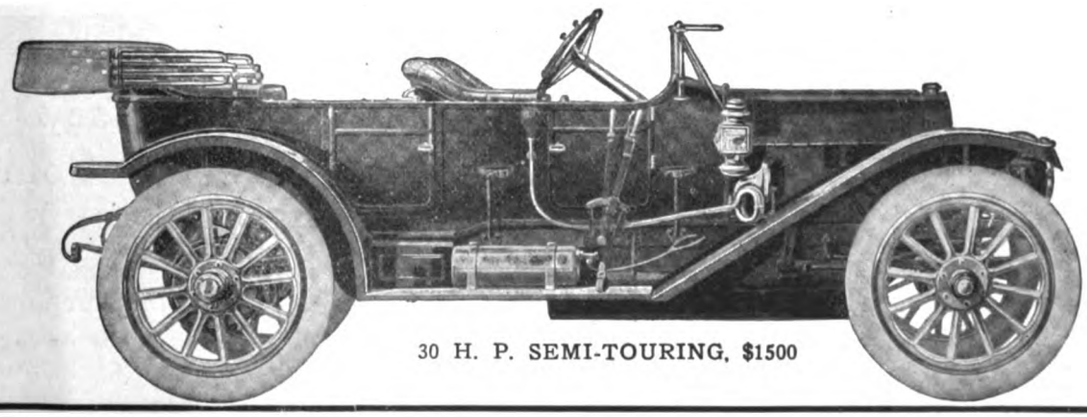
KisselKar service is nation-wide. Included in the KisselKar service organization are especially constructed and equipped service buildings at principal points of America. These are service branches of the Kissel Motor Car Company, bringing every KisselKar owner into close relationship with the manufacturers to whom **service to owners** is an important policy.

These branches carry a full stock of parts of every KisselKar model ever built, so the shaking loose and loss of minor parts, or even serious breakages through accidents, do not involve long waits for replacements. KisselKar Service takes care of you wherever you are.

Here is a Partial List of KisselKar Service Branches and Sales Agencies.

Boston, New York, Philadelphia, Cleveland, Detroit, St. Louis, Dallas, El Paso, San Antonio, New Orleans, Baltimore, Chicago, Milwaukee, Kansas City, Omaha, Butte, Denver, San Francisco, Los Angeles, Seattle, Portland, Minneapolis, Duluth, Buffalo, Pittsburgh, Hartford, Conn., New Haven, Albany, Troy, Montreal, Quebec, Toronto, Winnipeg, and 200 other principal points throughout the United States.

KISSELKAR



30 — $1500
40 — 1850
50 — 2000
60 H. P. "Six" — $3000

KisselKar prices, except on the "Thirty," include full equipment—top, glass front, demountable rims, speedometer, etc.—everything needed for a perfectly dressed car. The "Thirty" has more than regular equipment.

Write for KisselKar catalog, illustrating and describing the KisselKar line of pleasure models, and commercial vehicles. It is one of the most comprehensive books ever published.

Ford
THE UNIVERSAL CAR

At 6's and 7's the world is sure to be—to him who has not learned to center his effort. We will make—and sell—seventy-five thousand Ford cars this year—because we have concentrated our energies upon the building of one—and only one—good car.

And today there is no other car like the Ford Model T. It's lightest, rightest—most economical. The two-passenger car costs but $590, f. o. b., Detroit, complete with all equipment, the five passenger but $690. Today get Catalogue 101—from The Ford Motor Company, Detroit, Mich.

K·D

The Motor With the Sliding Crescent Valve
KNIGHT-DAVIDSON
1896 — 1912

The **CRESCENT valve** of the **K-D Motor**, fitting around the stationary piston wall affords a larger port area than any other poppet or slide valve on the market. It is simpler and, consequently, better than any other valve construction known and is here offered to discriminating manufacturers, not as an experiment, but as a tried, tested and proved mechanical advance. The **K-D motor** is **simple, silent, cools rapidly**, has the **simplest** oiling system known, will not **carbonize.** Last and most important, will give on a given quantity of fuel more **power, speed** and **endurance**, unit for unit, than any other engine on any type of an automobile. We want to present some **facts** to interested manufacturers.

SPECIAL METAL STAMPINGS

Digitized by Google

QUANTITY and QUALITY

On The Acme Automatic Multiple Spindle Screw Machine

THE quality of parts used by the Automobile trade must be excellent in order to stand the test.

We have placed in the plants of the largest Auto manufacturers in the world, Acme Automatics, which are not only helping to give the manufacturers a fair profit, but are partly responsible for standardizing of high grade equipment.

The simultaneous use of as many as eight tools is the principle which stands for both quality and quantity in this screw machine.

When especially fine diameters are required the method provides for the setting of a special tool in one of the eight positions for shaving, reaming, etc. These extra operations, which can be applied without loss of time, are what make this machine preferable to consumers.

May we prove quality and low cost on your work?

PITTSFIELD

High Tension Magneto

Press the Button—Your Car Starts

THE REMARKABLE freedom from breakdowns, due to its unique design, has brought the Pittsfield true high tension magneto into extraordinary popularity among motorists

It has no moving wires on the armature, the coil being stationary in the rear of the magneto and watertight. Not only is the retarded spark as efficient as the advanced, but our latest design is operated by a Self-starting Switch that makes cranking unnecessary.

Equip your car with our Type N-B and it will start easier, run better and take steeper hills on high gear than ever before.

The Lightest, Practical Rim Made

It Is Not Enough to Specify Demountable Rims For Your New Car—Insist Upon

"Firestone"

Quick Detachable

Demountable Rims

Built from the Tiremaker's Standpoint and Experience

Look into the past records of demountable rims; see how long any one of them has withstood the test of time; find out from users which one is most practical and dependable in **actual service.**

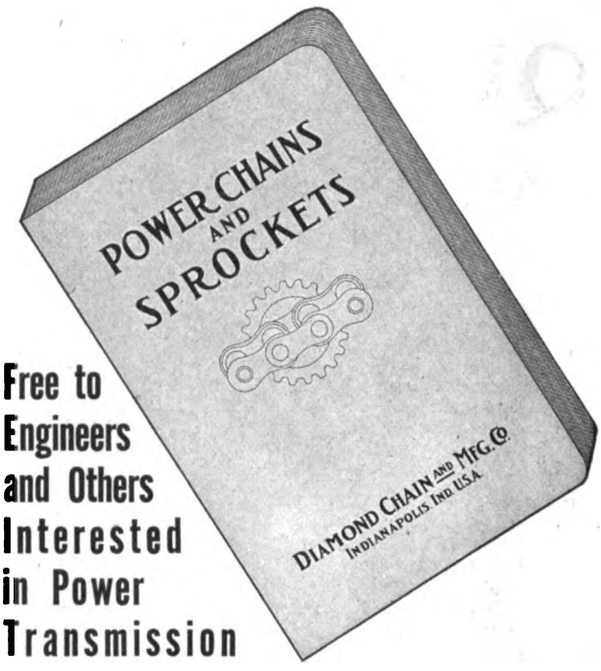
We have no doubt as to your decision. Other rims have come and gone, while the Firestone has steadily gained in leadership. You will choose the Firestone—

Because the Firestone rim has a **continuous** bearing-support all around the wheel. The Firestone rim has no wedges placed here and there to force it out of round.

Because the Firestone rim has a "no-split" or unbroken base that makes it water-tight—keeps moisture from working through and decaying the tire.

Because the design of the Firestone rim does away with all complications and delicate adjustments, absolutely preventing rusting together of parts, ensuring reliability and ease of operation, and requiring no special tool to operate.

Because the Firestone quick detachable feature enables you to change inner tubes when rim is on the wheel as well as off it. Think what that means when overtaken by repeated punctures.



Because several years of success have refined Firestone rims to the lightest weight consistent with safety and practicability.

The Reflex

An Inspection Light That Locates Trouble with the Least Trouble

MOTORISTS who have learned the trials and inconvenience of **crawling under** the body of the car to locate trouble will gladly welcome the advent of the "REFLEX"—the Inspection Light that will reach into the innermost recesses of the Motor, etc., and show, clearly, all sides of the object at one glance. It gives a powerful light without danger of explosion, without smoke or soot. It has done away with the dangerous match and candle. Can't blow out; costs little more than the ordinary pocket flash light. Our circulars and price lists will be mailed on request.

BIG THING FOR AUTOMOBILE SUPPLY DEALERS

REFLEX INSPECTION LIGHT SALES COMPANY

SOLE SALE RIGHTS FOR UNITED STATES

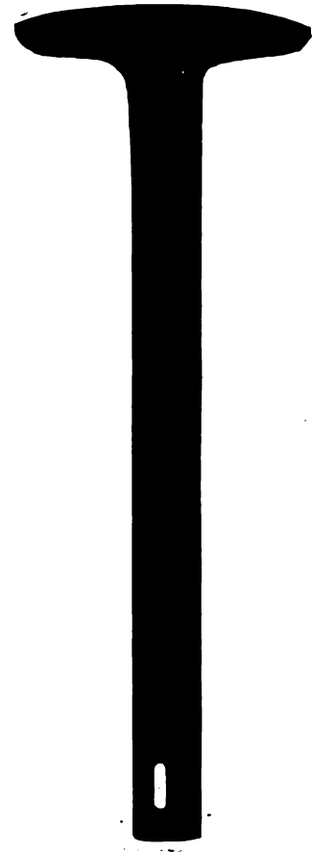
35-37 S. Third Avenue **Mount Vernon, N. Y.**

THINK THIS OVER very carefully and read it twice, if necessary.

Is there any part of an automobile engine, or any other gas engine, that is more important to its efficiency than a Valve?

Your engine leaves the factory running smoothly and sweetly—tuned up to its highest power. Perhaps the valves pit—warp—go out of shape—fail to hold compression. Then the power diminishes, and what can be more aggravating to the driver, who has known the fullness of the pulling power of his motor, than to have it grow less and less?

You cannot slight this part by putting in an inferior product—valves that will give trouble, or even break from inexperience in their manufacture—valves of unsuitable material, not suitably heat treated.



Too much is at stake, and a slight extra cost at the outset, which is the exception, may save you many times over a probable later expense.

This Company, with the experience of many years as a guarantee, will furnish you with properly made valves, of the materials best adapted to your requirements.

Not only QUALITY, but efficient SERVICE is a factor—surely there is a satisfaction in getting the kind of work you want—when you want it.

WHITNEY

The Most Practical Chain for Motor Trucks

Because the "Whitney" Cotter Detachable Chain can be easily separated at any link and lengthened, shortened or repaired without the use of any special tool. This is of great advantage to truck builders, owners and drivers.

To have your truck equipped with "Whitney" Chains means greater mileage because they are made by specialists in a factory especially equipped for the making and are backed by years of experience. "Whitney" Chains are made from material chosen for quality regardless of cost, and all care taken in their manufacture makes them stand foremost. When making replacements try a "Whitney" and get acquainted with its merits.

Mr. Automobilist:

Your tire maker is very anxious to impress upon you the importance of

Tires Inflated to the Right Pressure

He insists that this is tire economy and

Saves You Money

How do you know what pressure you have in your tires? A

SCHRADER
UNIVERSAL
Tire Pressure Gauge

(Trade Mark Registered in U. S. Patent Office)

(Patented March, 1898—Other Patents Pending)

will tell the exact pressure in your tires at any time, day or night, by simply holding this Gauge to your Valve for a second. Its recording sleeve remains in place, showing the exact pressure in the tire so that the Gauge can be taken anywhere and read, at night to the front of the car into the light of the lamps. After the pressure has been ascertained the Indicating Sleeve can be pushed back into the Gauge with your finger. No catches or snaps to operate or get out of order. This Gauge is 2½ inches long over all, short enough to apply easily to the smallest diameter of wheel and can easily be carried in the vest pocket or the change pocket of your trousers.

Price $1.00 Each
Ready for Delivery Now

Guaranteed Simple and Absolutely Accurate

Can be obtained from all tire manufacturers and the dealers, or

Diamond Tires

We could build them cheaper But We Won't

We would build them better But We Can't

ONE big advantage in favor of the dealer who sells Diamond Tires is this:

¶ Diamond Tires include any and every type and style of tire that car owners want, and every Diamond Tire sold builds prestige for all the others.

¶ Diamond Tires are made in all types to fit all styles or makes of rims. The Diamond types are Clincher, Quick Detachable, Mechanical (or Straight-side) and Fisk.

¶ In treads the Diamond dealer can offer the famous Diamond Safety Tread, the regular Smooth Tread, Bailey Tread and Grip Tread.

¶ Every type, every size, and four treads all included in one famous make of tires, and every tire no matter what the type or tread gives the greatest mileage and the best service that can be bulit into a tire.

¶ This is the Diamond dealer's advantage—can you beat it?

If you are not receiving our little magazine for dealers you're missing something good. Send your name—it's free to dealers.

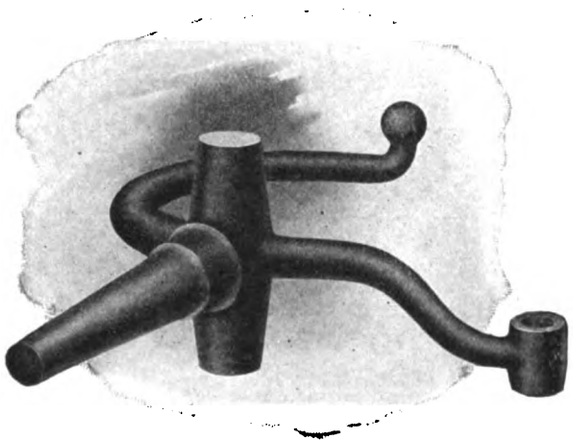
B & L CASTER FRONT AXLE

Makes a Big Winner in Philadelphia

Our Philadelphia Agent writes it is a Great Success.

A. S. BURNELL, President and General Manager, 1346 Michigan Avenue, Chicago, Ill.

Philadelphia, Pa., February 28, 1912.



Dear Sirs:—The axle is a great success, is running fine. Have made several demonstrations and every one says it's the only front axle that ought to be allowed to go on the automobile, for safety, easy steering and perfect control. Will sell the majority of those I have demonstrated for. Enclosed you will find order for one axle to go on a Studebaker car, 1908 model, more orders will follow later. Send us a big cut for we are going to run a one-half page in our newspaper, we will advertise it right. We will equip at least one thousand cars this year. Our new garage will be at 1907 after March 12th, N. 23rd St. Circulars received all O. K., thanks for same. Rush the order for axle, as every one on a car will sell several more. Yours very truly,

H. SCHROEDER,

Philadelphia, Pa., 1418 Blavis St. President and General Manager Lake Schroeder Auto Exchange.

AGENTS WANTED for all cities in the United States to put the B & L Caster Front Axle on old cars. Exclusive territory given to good men. Our axle when on a car proves that it is the only safe axle made. In buying a new car demand that it be equipped with the B & L Caster Axle. Write for Agency Proposition. Address:

A. S. BURNELL, Manager Chicago Branch, 1346 Michigan Avenue.

Polarine

The Best Oil for All Motors

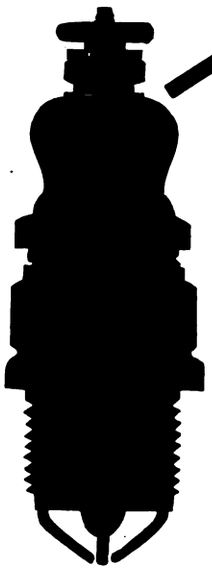
When a car starts out lively in the morning and then shows signs of sluggishness later in the day, it usually means something is wrong with the lubrication.

Use **POLARINE** Oil and you will avoid two-thirds of all motor troubles.

POLARINE is the best automobile oil yet produced.

It gives the maximum lubrication for the amount used. It insures the least possible friction and wear, with full compression and power.

It leaves no carbon deposit.



It feeds freely right down to zero.

Look for the flat, convenient can —just fits in the tool-box. Ask your dealer.

Our free booklet tells all about the Polarine Brands, and contains many useful hints on the care of a car. Write for your copy today to any agency.

CHAMPION IGNITION COMPANY

FLINT, MICHIGAN

REMY

Inductor

This is the laminated fan-tail inductor. Thin sections of special lamination steel (insulated to prevent eddy currents and electrical loss) are pressed into one solid indestructible unit. It is keyed to the steel inductor shaft with Woodruff key. One inductor revolves on each side of the stationary winding, generating electrical impulses in the winding.

Can not wear or get out of true. The sturdiness of the inductor is characteristic of the entire magneto—the keynote of unfailing Remy Ignition Service.

If You Need Motor Lamps

You Need This Catalog

We want you to write for the Solar Catalog before you decide on your motor lamps, for this is the most complete line of lamps on the market. Solar Lamps have been preferred by most motorists for the past fourteen years because of their brilliancy, their style, their strength and their several exclusive advantages—their special short focus lead glass lens mirror reflectors—the patented double ray light projection (in the Solarclipse), giving two distinct fields of light, for city and country use—the new black finish, the only such finish that's proof against heat and moisture—and other features that other lamps lack.

To fail to see Solars before you buy is to fail to include in your consideration the very finest lamps in existence. Solars are made for oil, electricity, gas and in combination, for pleasure cars, motor trucks, carriages, motor boats and airships. Write for catalog now—while you think of it. (136)

SHAWMUT TIRES

SOLD EVERYWHERE **SHAWMUT TIRE CO., Boston, Mass.**

Digitized by Google

Woodworth Treads

are distinguished from apparently similar devices in THREE important particulars.

1. They are at least 50 per cent. more durable. The life of the best tire protector is the life of its middle rows of rivets. Those of WOODWORTH TREADS have heads glass-hard clear through, not soft like those of other makes.

2. The chrome leather base of WOODWORTH TREADS is impregnated, not with oil, but with a special filler which never dries out and which keeps the leather always soft.

3. The best-made protector is worse than useless if it stretches loose and chafes the tire. WOODWORTH TREADS are drawn always snug by strong side springs. They cling to the tire as if a part of it; no stretching can loosen them.

So closely do Woodworths hug the tires that even dirt cannot enter to do harm. The tendency is always to squeeze it out: if any crumbs remain, they are quickly rubbed to a smooth flour-like paste. Thousands of miles barely mark the rubber.

Woodworth Treads avert skidding and its dangers. They prevent wear, cuts and punctures, and eliminate fabric rotting by keeping the rubber whole. They cost about half as much as tires and last as long, New tires protected by them last about three times as long as when run bare. They save from ¼ to ½ of the tire mileage cost and all tire annoyance.

SPECIAL to DEALERS

We will send any rated dealer or garageman a pair of Woodworth Treads on 30 days' trial. If not perfectly satisfactory they may be returned at the end of that time and the charge will be cancelled.

Write for reduced 1912 prices and our booklet, "The Preservation of Auto Tires."

FISK

Heavy Car Type Tires

For Any Rim

Consumers' Prices Reduced
Quality Unchanged

Size	Casings: Clincher, Q. D. or Dunlop Price	Casings: Bolted-on Price	Tubes: Clincher, Q. D. or Bolted-on Price	Tubes: Dunlop Price
3½ x 30	$20.35	$24.85	$ 4.90	$5.15
4½ x 36	45.20	50.20	9.20	9.65
4½ x 37	46.50	——	9.50	9.95
5 x 36	55.50	58.60	10.20	——
5 x 37	57.00	60.20	10.60	——
5½ x 38	68.30	72.15	12.30	——

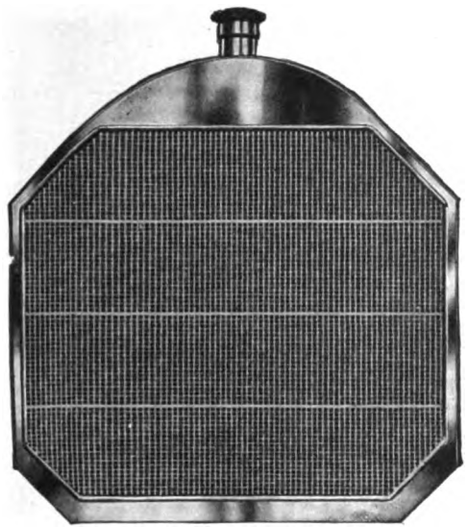
PERFORMANCE is the factor behind the success of Fisk Heavy Car Type Tires. Their rapidly increasing sale is due to the verdict of car owners who, once using them, buy again for their own cars and recommend them to their friends. "You are urged to inquire among many Fisk Tire users" because we can present no stronger argument than the everyday service Fisk Equipment is giving. MILEAGE and DIRECT REPRESENTATION combine to make the only service that really interests any buyer. It is THAT SERVICE upon which the success of Fisk Tires is founded.

The Fisk Tube is the Pure Para Tube

This accounts for the slightly higher prices, in comparison with other tubes, at which it is sold. The initial increased expense is slight—the resulting additonal service makes it a far better buy than any one of the many compounded tubes sold at a lower figure. We had but one choice—to lower our present standard and compound our tubes or to hold to present construction and maintain slightly higher prices than other makers. We have decided in favor of quality, believing it far more economical in the end for every buyer.

Two New Anti-Skid Tires

THE NEW FISK TOWN TREAD—Heavy Car Type—This tire provdes a heavy anti-skid tread designed to insure traction and affords the greatest possible protection against skidding. It is positive in action on city pavements and country roads and eliminates the necessity of chains with the attendant expense, noise and inconvenience.



THE NEW FISK BAILEY TREAD—Heavy Car Type—Heavy buttons and one more row than any other Bailey Tread on the market. This increases the anti-skid surface and length of service, as outside rows of buttons give anti-skid protection when center tread is worn down.

Fisk Heavy Car Type Tires Are Sold by All Prominent Dealers

TRADE-MARK

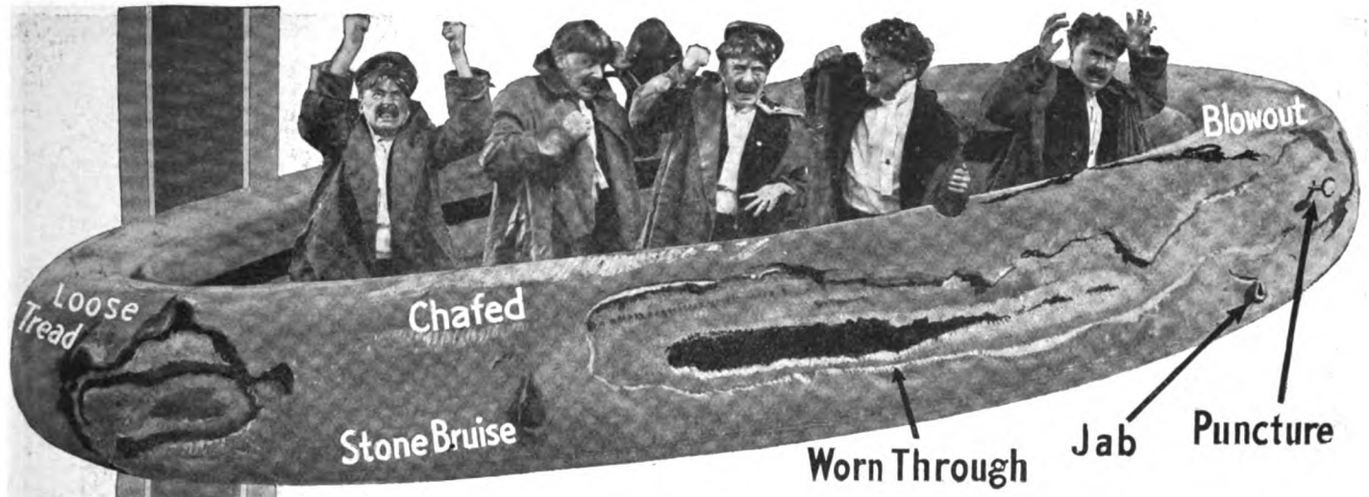
Champion Spark Plugs

CHAMPION X
75 Cents

Special inducements of all kinds and descriptions are offered by spark plug manufacturers in their efforts to increase their sales. Some guarantee their plugs to last forever (or furnish new ones); others boast of the fact that all parts are made by them and that they therefore must be perfect.

We base our claims of the "Champion" superiority upon the fact that over sixty per cent. of the manufacturers in America during 1912 specify Champion Spark Plugs. Ford, Overland, and over fifty other representative makers use the Champion plugs exclusively in their regular equipment.

When a majority of the leading automobile engineers of the country specify Champion plugs in preference to all others, there is but one logical conclusion to be drawn—Champion Spark Plugs **must** have the **goods** in them.



Leading dealers and jobbers carry Champion plugs. Insist upon the **genuine.** The world trade mark (shown above) appears on each box, and the name "Champion" is plainly marked on the porcelain.

Write for our interesting equipment proposition.

Save Those Tires—Old and New

NEVER another day—hour—or moment of tire trouble! "Head off" all tire troubles—stop them—before they come—just as you would insure your house before it burns.

It is good business—it is sound finance—it is common sense to apply Standard Tire Protectors to any tire, even before you give it a mile of road use. Standard Tire Protectors are not an accessory of the needless or novelty type—they are pure, common sense, business insurance, which carries with it freedom from tire-worries, delays and aggravations.

STANDARD TIRE PROTECTORS

will double the life of your tires and more! They are made of the toughest rubber known today. By applying these Protectors to your new tires, you save your tires from the wear and tear of road-contact. The Protectors will wear longer than the bare tires would wear—but when the Protectors eventually do wear out—then you have only to buy new Protectors instead of buying new tires at a greater expense.

Convert your plain-tread tires into non-skid tires without extra cost! These Protectors are made in non-skid tread as well as plain—a non-skid tread so made that it grips any road surface with claw-like tenacity, and **wears**, too. At one operation, without extra expense, you secure this unexcelled skidding protection, in addition to tire protection, when you apply Standard Tire Protectors to your tires.

Get Standard Tire Protectors instead of retreading your old tires. They will protect those old tires against punctures, blowouts, stone bruises, cuts, jabs and all such tire troubles. And besides, without extra cost beyond the price of the Protectors, you change an old, plain-tread tire into an almost new non-skid tire. As a business proposition from every standpoint—get Standard Tire Protectors **now.**

Reduced prices—average 20 per cent. lower than last year on all popular sizes—a further economy gained for you by our new manufacturing advantages, now remove the last reason for you to delay giving your tires this protection. Standard Tire Protectors may be had in all the regular sizes—to fit any tires. They are easily applied in just a few minutes—are held on tight and fast simply by inflation pressure—no mechanical attachments. Do not chafe the tire. Sand or gravel cannot get between the Protector and the tire. Get Standard Tire Protectors **NOW**—whether your tires are old or new—and **end** your tire troubles.

A Free Book on Tire Protection

will be sent you on request. It proves the five-dollar-for-one, and often higher, value to you of Standard Tire Protectors.

Dealers: More business and bigger discounts on Standard Tire Protectors. The old "bugaboo" of "Price too High," killed. Write us at once for particulars of our 1912 Sales Co-operation to Dealers, and new Price List.

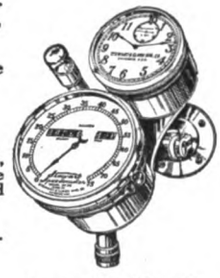
Not Equipped for the Part

A camel once saw a cat on his master's lap and was jealous of the petting the cat received. Wishing to take the same place in his master's affections, he tried to occupy the same place in his lap. His intentions were excellent but he wasn't equipped for the part.

It's *"equipment"* that counts in speedometer business.

The *Stewart Speedometer* has for years occupied the most prominent place in the *affections* of the automobile public. There are *other* manufacturers who wish to take the same position. Their *motives* are splendid but they aren't equipped for the part.



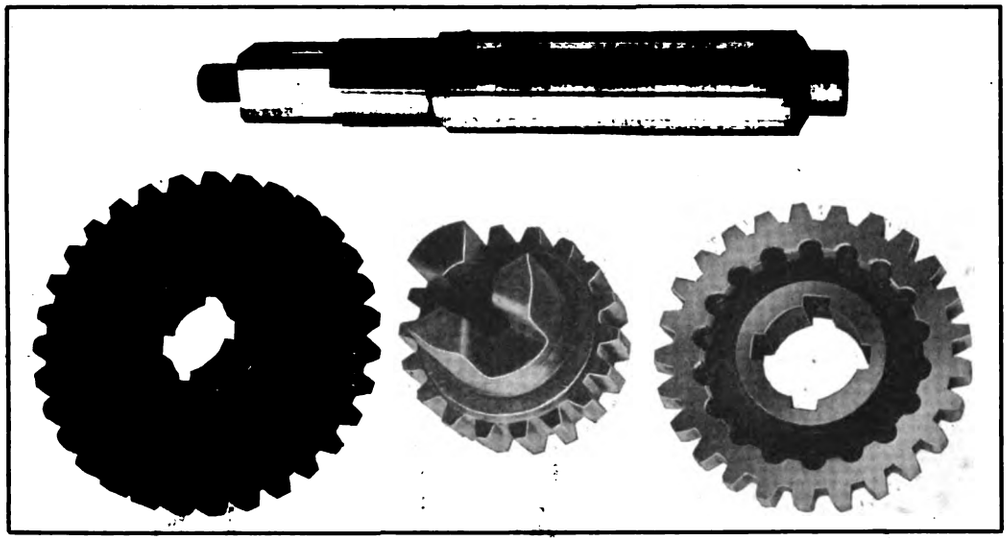
The Stewart Speedometer is built in the *largest* speedometer factory in the world. The factory's so *big* that the price is *small*, but the Stewart is the best *constructed*, longest *enduring*, and the most exquisitely *accurate* speed indicator on earth.

Wear proof, *weather* proof, *condition* proof. *Four* cars out of *five* carry the *Stewart*.

What better test to prove it best?

Magnetic principle; jewel bearings; wearing parts hardened and polished; open dial; large figures, easily read; absolutely accurate; 100,000-mile season odometer; 100-mile trip register, can be reset to any tenth of a mile. Guaranteed for five years. Strongest flexible shaft; drop forged swivel joint; noiseless gears.

"ALWAYS ON THE JOB"



Speedometers, $15 to $30
Rim Wind Clock Combinations, $45 to $70

A Small Edition of a $5000 Car for $850

The Empire 25 presents amazing opportunity to buyers as well as dealers. An $850.00 touring car with all the essentials of $5000.00 Cars except needless power and cumbersome size. The Big Brother of the Famous Empire Roadster.

Empire 25

The Little Aristocrat

This stunning little car—called "The Little Aristocrat" because of its striking design—is distinctly different from all other cars in the **sub-thousand dollar** class.

The Little Aristocrat has all the efficiency of the highest type cars. It is roomy—powerful—speedy—dependable. Five people can ride in ease and comfort and it has power enough to take them anywhere. No hill can stop it. It will travel 40 miles an hour. In short it enjoys every advantage had by the best of small cars and one advantage that none of them has ever approached.

For this car is not only efficient but **beautiful** as well. It has been graced with the same distinctive lines of beauty and character that have lent exclusiveness to cars of the five thousand dollar class. It **is** a $5000.00 car as seen through a reducing glass—a small car of **real quality** built for big car owners as well as for those whose means have been unequal to the high initial cost and the heavy drain made by all **large** cars of The Little Aristocrat type.

How We Got Our Design

The design of The Little Aristocrat is one of its most distinctive features. It is the result of a contest in which we offered a prize to the body designer whose specifications we accepted.

Nor did we stop with the mere **design.** We carried our **big idea** into the **finish** as elsewhere—finished The Little Aristocrat in Empire **Blue** and **Black Enamels,** the royal sign of **Quality.**

The upholstering we made **luxurious** and inviting. The seats we made **extra** wide and deep and the spring cushions **extra** thick and comfortable.

The doors also we made extra large, and with inside handles to facilitate getting in and out. Interior equipment throughout is only such as to please the most fastidious.

The dash and cowl we made of aluminum in one piece, thus following the custom of the **highest priced cars.**

The Steering Wheel we built extra large. It is 17 inches in diameter; most cars have 15 inch Steering Wheels.

The Steering Knuckles as well as the **axles** we made extra heavy for greater strength and safety.

The Clutch is disc type, Raybestos, 9 inches in diameter instead of 5, the kind commonly used on cars of this **size.**

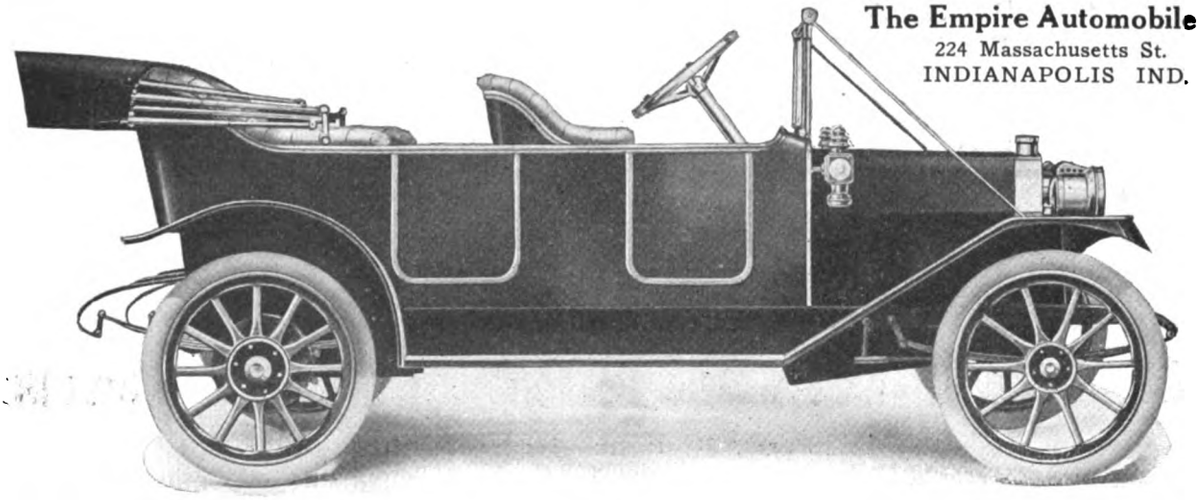
Big Hubs for style—big Artillery Wheels equipped with Big Tires for easier riding, tire saving and maximum ground clearance—a free running board and fenders of the most approved type, serve to put class and character into this car.

In short we gave this car a **distinction** all its own.

No other car is like it.

SPECIFICATIONS OF THE EMPIRE 25

Motor—25 H. P., 3½ inch bore, 4½ inch stroke—cylinders cast in pairs.
Cooling System—Large radiator in conjunction with a belt-driven fan. Circulation effected by the thermo-syphon method.
Valves—Fully enclosed, adjustable for wear.
Lubrication—Constant level, force feed.
Ignition—High tension magneto, set spark.
Clutch—Disc clutch, dry plate type, Raybestos faced.
Control—Single lever center control. Throttle lever above steering wheel. Clutch service and emergency brakes operated by foot pedals.
Steering—Full worm and gear type.
Brakes—Two external, contracting. Two internal, expanding on rear wheels.
Transmission—Three speeds forward and reverse, selective type, mounted on annular bearings. Unit power plant.
Gears—That are silent even when shifting.
Rear Axle—Semi-floating type.
Front Axle—I-beam section, drop forged. The size of the steering knuckles would do credit to a car twice the weight of the Empire.
Springs—Three-quarter elliptic rear, semi-elliptic front.
Wheel Base—104 inches.
Wheels—Selected second growth, artillery type, 32 inch quick detachable rims.
Body — Aluminoid steel, wood trimmed; fore-door, full vestibule, straight lines from front to rear, ample room in tonneau, seats wide and deep, buffed leather cushions comfortably slanted, inside handles on doors.
Frame — Pressed steel, channel section, dropped, giving low center of gravity and easier riding qualities.
Gasoline Tank—Capacity, 12 gallons.
Standard Equipment — Includes magneto, gas lamps, side oil lamps, tail lamp, tools, repair kit, tire pump, jack and horn.



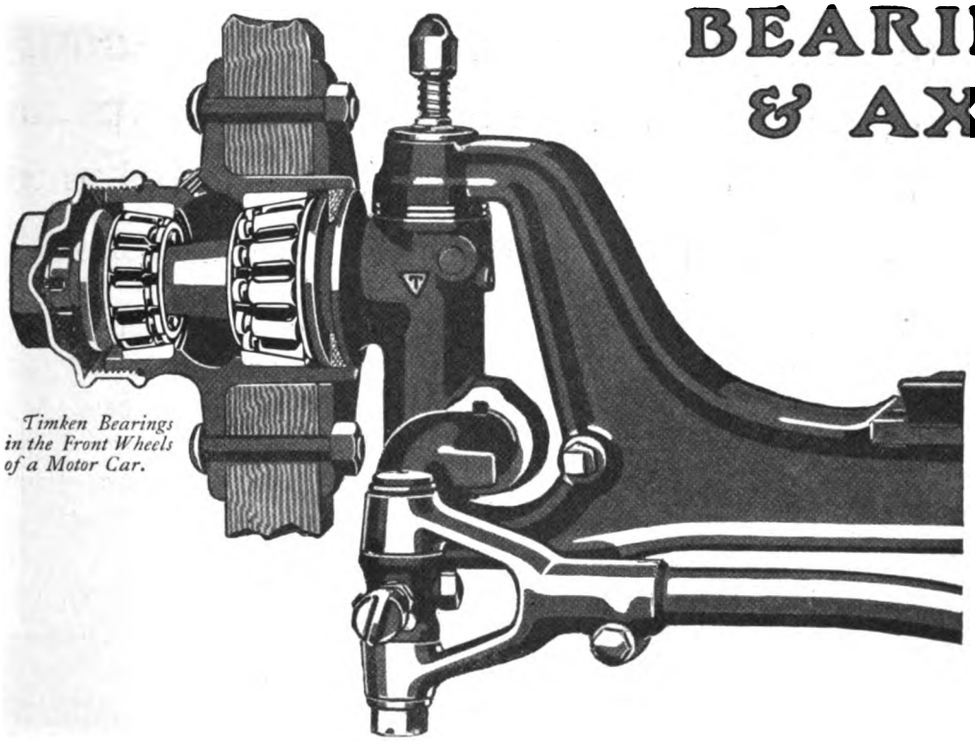
A Market of Half a Million

Dealers everywhere are showing a rapidly increasing interest in this wonderful little car.

Never before has a car been offered that presented such astonishing possibilities. Its low price and unequaled quality are points found in no other car.

Thousands will buy Little Aristocrats this year and tens of thousands next year. Every community will have its owners. And every dealer who handles them will experience a wonderful "picking up" in his automobile business.

The most liberal proposition is waiting for you to ask for it. Write at once.



The Empire Automobile Co.

TIMKEN

BEARINGS & AXLES

Timken Bearings in the Front Wheels of a Motor Car.

Right here—the point of hardest service—Timken Bearings proved the correctness of their principle and won their way to other uses.

Do you know what your front-wheel bearings have to meet when your car rounds a corner?

The whole weight of the car and its load is suddenly and violently thrown toward the outside of the curve.

The front-wheel bearings get almost the whole of this tremendous pressure—called "end-thrust."

On a rough road the swerving and jolting of the wheels is practically constant.

Every stone, every rut, means a sledge hammer blow on the bearings—first one side, then the other.

Only bearings that can stand this end-thrust—Timken Tapered Roller Bearings—will do for front-wheel service.

Timken Superiority Depends on Correct Principles

Timken Bearings have the greater strength—the greater capacity for hard service—because their tapered rollers carry the load along lines instead of on points as balls do.

They meet end-thrust as easily as weight—because they are set at an angle to the shaft.

No matter whether the force comes from above or from the side, it can never meet the roller end-on, it is always resisted by the long supporting area of contact.

Another great Timken Bearing advantage is resistance to wear.

Of course wear will come sometime—no bearing could be made that wouldn't wear.

But the Timken Bearing *can be adjusted to take up that wear* by advancing the cone into the cup.

Timken-Detroit Axle Construction Completes Your Assurance of Safety and Satisfactory Driving

Because Timken policy overlooks *no* factor in safe and sure axle building.

The little things are there as well as the big.

We believe Timken alone has them all.

And that is why they are today meeting the test of actual service in thousands of cars of every type—pleasure and commercial.

Digitized by Google

Never in the history of the tire industry have prospects for a coming season's business loomed up as bright as they do today before every United States Tire dealer.

Possibly because never has a tire dealer received such substantial "backing from the manufacturer as the United States Tire dealer is getting today.

The "backing" which he gets in the matter of tire quality alone is enough to win for him the predominating place in the tire trade of any community. Motorists are not long in finding out that the four-factory co-operative methods employed in building United States Tires give to a tire strength and stability that can be put into it in no other way.

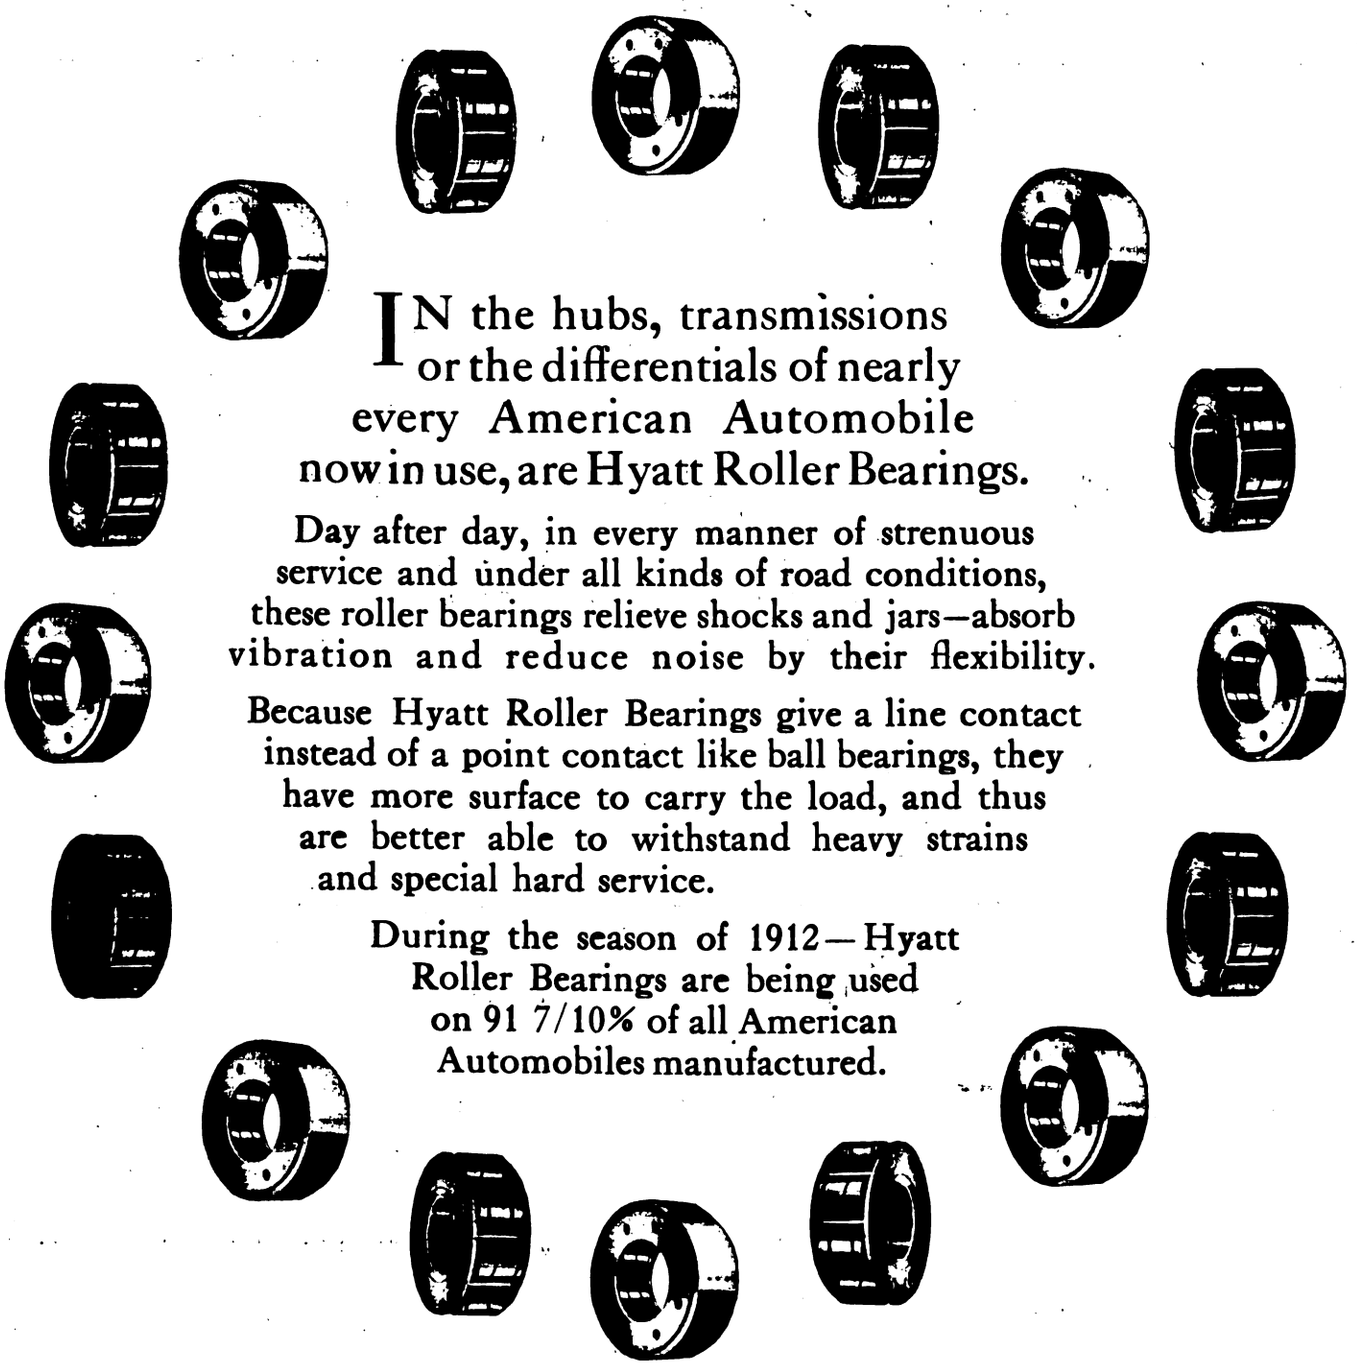
But add to this quality advantage the absolute protection in the retail field which the United States Tire dealer now enjoys—the first and only protection ever offered to a tire dealer by any manufacturer.

Add to this an established consumer demand built up thru a decade spent in good tire building by the four separate companies—strengthened by the past remarkably successful year under the new organization—and now focused on the store of every dealer who handles

UNITED STATES TIRES

Then you will realize why the best dealers in this country have been won over to United States Tires in a body. Four out of five are now handling them.

We are facing a season that promises to be one of the most successful in automobile history. Over half a million cars are on the road calling for an aggregate number of tires well over the two million mark. You owe it to yourself and to your business to get all the help possible in capturing the bulk of this trade in your territory.



Decide for yourself which among the tire makers is in a position to give you the most.

UNITED STATES TIRE COMPANY

ROLLING
ROUND and ROUND

IN the hubs, transmissions or the differentials of nearly every American Automobile now in use, are Hyatt Roller Bearings.

Day after day, in every manner of strenuous service and under all kinds of road conditions, these roller bearings relieve shocks and jars—absorb vibration and reduce noise by their flexibility.

Because Hyatt Roller Bearings give a line contact instead of a point contact like ball bearings, they have more surface to carry the load, and thus are better able to withstand heavy strains and special hard service.

During the season of 1912—Hyatt Roller Bearings are being used on 91 7/10% of all American Automobiles manufactured.

"The Horn that's Made for the Discriminating"

TUTO HORN

THE TWO TONE HORN

Withstands All Climatic Conditions

THE bulb horn is inadequate in many ways. It is effected more or less by heat, cold, dirt, water, etc. Its operation is more or less difficult under varying conditions of travel, because of the use of robes in winter, storm curtains in bad weather, etc. Usually, when most needed it is least responsive. Then the signal note has been declared inadequate for a safe warning signal on a modern motor car.

¶ Exhaust horns depend entirely on the speed of the engine, the ability of the driver to have a free foot for operating the lever, and in case of emergency, a hand or another foot free for speeding up the engine so as to get a loud signal note. In case of emergency, such action is absolutely impossible and the exhaust horn fails utterly as an adequate signal.

¶ The TUTO electric horn operates without any decrease in efficiency under all climatic conditions, and regardless of the presence of robes, storm curtains, etc. The TUTO will give its signals, low or loud, just when needed, as the operating button is located on the steering wheel right under the thumb. It is always accessible and does not require the moving of a hand or foot, just the pressure of the thumb.

¶ There are no pivots, bearings, brushes or other parts to require constant attention, and to become clogged with dust or damaged by water. Furthermore, the TUTO horn is always under constant test. The same horn, the same button, the same cord and same battery which is used in making the low note (service signals used in place of bulb horn) are employed in producing the loud emergency signal.

¶ The TUTO is always on the job and is absolutely dependable, regardless of adverse climatic conditions. This makes the TUTO horn essential as standard equipment for all motor cars.

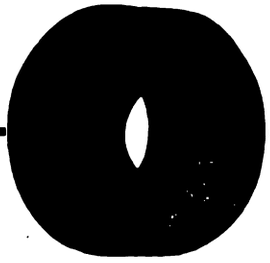
MAY WE HAVE YOUR LAYOUT

Of Bearing Installation?

¶ We can save you money, time and trouble—in other words, show you a short cut to satisfactory bearing installation.



¶ The successful use of New Departures in 60% of the motor cars manufactured in this country proves that the quality of this American made bearing has been well established.

¶ This fact also constitutes a good reason why you should send us your layout and give our engineering and sales departments an opportunity to place our proposition squarely before you.

¶ Our engineering department is highly specialized, not only for the production of superior ball bearings, but for giving to the trade expert co-operative service.

The New Departure Mfg. Company

Self Starter HANNA

BECAUSE the Hanna Self Starter accurately measures and then mixes your gas in the cylinders of your gas engine explains why it is the only 100 per cent. efficient self starter and one that does not foul or soot your plugs.

The first acetylene starter on the market. The only 100 per cent. efficient self starter.

Don't confuse the Hanna with any manifold starter that charges your engine as it stops. The Hanna Self Starter puts gas into the cylinders of your engine when you are ready to start the engine, not the week before, the day before or the night before.

The Gas Lighter alone is worth the $10

But we give you both gas lighter and manifold self starter for the one price of $10. And we fully guarantee our offer, too. Don't make any mistake about that. We guarantee the Valentine manifold starter just the same as we do any other of our products. There isn't a single manifold starter on the market that's any better than the Valentine and few so good.

No manifold starter at any price is better than this at $10.

We sell the Valentine Manifold Starter and electric gas lighter for $10 because that's all it's worth. That's all any manifold starter is worth. The lighting device is thrown in for good measure to make our offer a real bargain.

Dealers—This is the greatest chance you'll ever have. Better get your hat in the ring before it's too late.

J. H. VALENTINE CO., Syracuse, N. Y.

The Valentine MANIFOLD STARTER and Gas Lighter

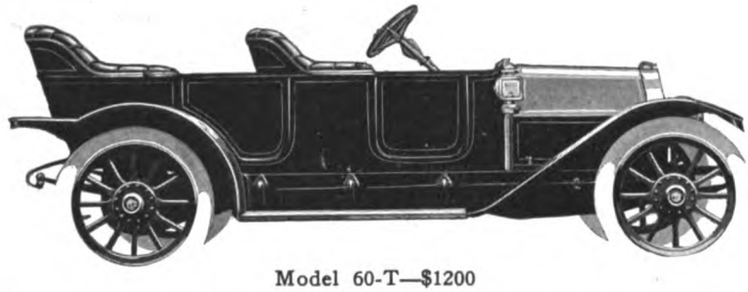
Overland



THE greatest difference in popular priced cars today is the difference in price. And this is entirely due to the size of the plants that produce them.

Our thirty-five horsepower touring car is priced at $1200. You seldom find a car of this size and type much below $1500 for the very simple reason that no other factory can produce it for this price. If they could they would. So why should you pay the difference?

Compare values and you will quickly realize the utter folly of paying $1500 for a car that can offer no more than our Model 60 at $1200.

Write for a catalogue. Please ask for book 1-44.

The Willys-Overland Company, Toledo, Ohio

Model 60-T—$1200

Wheel base, 111 inches; body, 5-passenger fore-door touring; motor, 4⅛ x 4½; horsepower, 35; Remy magneto; tires, 34 x 4 inch Q. D.; equipment, three oil lamps in black and brass finish, two gas lamps, horn and generator. Self-Starter, $20 extra.

THE MOTOR WORLD

Vol. XXXI New York, U. S. A., Thursday, April 11, 1912. No. 3

TIRE FACTORY ON PACIFIC COAST

Building Already Erected in San Diego, Cal., and Equipment Now in Progress —Spreckles Family Interested.

After several false alarms which have been sounded during a period of ten years or more, a full-grown automobile tire factory is actually to be erected on the Pacific Coast, and under auspices that are not to be denied. As a matter of fact, the Savage Tire Co., which is the title of the project, was organized several months ago, and, without any considerable display of printed fireworks, has been constructing a considerable factory in San Diego, Cal. These buildings have just been completed, and the necessary machinery is being installed as rapidly as it is received from the machinery manufacturers in the East, with whom the orders for the factory equipment were placed.

Despite its location far from what is considered the center of the tire industry of this country, that the San Diego project must be accepted seriously and that the Savage Tire Co. is entitled to more than respectful attention is indicated by the personnel of its official staff. Arthur W. Savage, who was identified with the Savage Arms interests, is president of the company, and John B. Spreckels and Claus Spreckels, the multi-millionaires who made their immense fortunes in the sugar business, are vice-president and secretary, respectively. W. P. Book occupies the post of treasurer.

For some time reports have been afloat that these gentlemen were very much enamored of a non-puncturable tire embodying unusual material or of unusual design, and President Savage informs the Motor World that these reports have served to bring uncounted thousands of inquiries, to which, however, no reply has been made. For the present, the Savage Tire Co. will say nothing definite concerning the nature of the tire which it will produce, nor will it be ready for marketing for several months.

Empires to Be Made in Three States.

According to Hoover Holton, sales manager for the Empire Automobile Co., the new Empire "25" is to be manufactured in three different parts of the country. One factory now is in operation at Greenville, Pa., where 1,000 cars will be built this summer, with deliveries to begin by April 15th. The other two factories are to be operated in Indiana and Missouri. In the former, the site will be in either Indianapolis or Knightstown, while in the latter the cities under consideration are Kansas City and St. Joseph. The general offices of the company will remain in Indinapolis indefinitely, if not permanently.

Goodyear Declares 100 Per Cent. Dividend.

In Akron, O., where uncommonly luscious "melons" ripen in tire factories, another choice fruit has been prepared for cutting, the directors of the Goodyear Tire & Rubber Co., at a meeting held yesterday, 10th inst., having voted to distribute a stock dividend of 100 per cent. The distribution of this "melon" will be made possible by an increase of capital from $6,000,000 to $15,000,000. The proposals will be submitted to the stockholders for ratification at a meeting which has been called for May 28th.

Dyneto to Remove Plant to Syracuse.

Having outgrown its factory in Elbridge, N. Y., the Dyneto Electric Co., manufacturer of the electric lighting system of that name, is preparing to remove to Syracuse, N. Y., where a larger plant will be located. Several sites are under consideration, one of which probably will be definitely selected within the next few days.

Light Truck Coming from "Up-State."

Cram & Sovereign, of Geneva, N. Y., have embarked in the manufacture of motor trucks. They have a 1,500-pound wagon almost ready for the market. It is reputed to incorporate a number of particularly desirable mechanical features.

TIRE PRICES SET TRADE AWHIRL

Goodrich and Fisk Spring Surprises But Goodrich Surprises Even Fisk—Reductions Instead of Increases and End Not Yet in Sight.

After several days of feverish activity, during which the rush to place orders for tires, in anticipation of an increased price, reached astonishing proportions, that overwhelming portion of the trade which has to do with tires awakened with a start on Sunday last. For on that day, in the form of conspicuous advertisements in the daily press of all of the larger cities, the B. F. Goodrich Co. threw a price bomb, the effects of which it is as yet impossible to measure. Instead of an expected increase, the Goodrich company announced a reduction of approximately 16 per cent., not in its trade prices but in its prices to the public.

The Goodrich intentions had been so well guarded that not even the big company's chief competitors anticipated a move of the sort. They were taken wholly by surprise. The resulting conferences which were called in haste are still in progress. It is fairly well settled, however, that the Goodrich figures will be quite generally met, and that all of the great volume of orders which was invited or placed last week, in anticipation of an increase, will be taken care of at the newer and lower quotations.

Last week, as the Motor World exclusively announced, the Fisk Rubber Co. scheduled an increase in the price of its productions which, it was stated by those in position to know, would apply, however, only to trade prices and on tires of 3 inches and less, and on all inner tubes, the catalog figures being left unchanged. The new discounts were to become effective on Wednesday, 10th inst., and foreknowledge of the fact served to cause a great rush to cover, dealers and jobbers buying heavily and other manufacturers inviting orders in

Digitized by Google

anticipation of the general increase which seemed so plainly foreshadowed.

On Monday, the Fisk revised list was placed in circulation and disclosed that instead of an advance applying merely to the smaller tires and to trade prices, list prices had been pared from top to bottom.

As the Fisk branches had been officially advised last week of the intended and restricted increase, the reports that caused the heavy buying last week were well founded. What caused the Fisk company so suddenly to change front is not known, but apparently the Goodrich company became possessed of advance knowledge of the Fisk new list, and promptly proceeded to surprise the surpriser, so to speak. At any rate, when on Sunday the Goodrich announcement appeared with the reduction, which brought down the 34 x 4 from $37.75 to $31.30—$2.30 less than the Fisk price—and all others in proportion, the trade was placed at sixes and sevens and it has not yet wholly straightened out itself.

Yesterday, the United States and Diamond companies met the Fisk quotations.

Most of the other tire manufacturers are either "up in the air" or are in conference with their respective staffs, but, as stated, the intimation has been permitted to gain currency that practically all of them will meet the Goodrich list. As a matter of fact, few of them can well afford to do otherwise.

The market has become so unsettled by the unexpected turn of events that there is comparatively little buying by the trade. Such orders as are being placed are being booked conditional on the maintenance of present prices, and on lower ones should the pendulum swing that way, as some of those identified with the industry appear to think will come to pass. Heretofore the larger tire manufacturers have operated in sympathy with each other, their prices, due to "telepathy" or other causes, having been the same. The "waves" appear to have gone wrong on this occasion, however, and there are those who will be disappointed if a rare old fight does not result.

The extent of the new quotations is illustrated by the figures prevailing on the more popular sizes, as follows:

Size	Goodrich	Fisk-U. S.	Old Prices
32 x 3½	$21.20	$21.70	$24.40
34 x 4	31.30	33.60	37.75
36 x 4	33.35	35.80	40.25
36 x 4½	42.05	45.20	50.75
36 x 5	51.65	55.50	62.30

The prices of tubes, too, have dropped in approximately the same proportion to the drop in the price of casings. Goodrich 32x 3½ tubes now list at $4.50, with the price of U. S. and Fisk tubes of the same size 15 cents and 65 cents higher, respectively. The old price was $5.20. The Goodrich price for 34x4 tubes now is $5.95, and the U. S. and Fisk prices are $6.40 and $7.05 respectively; the old price was $7.15. Though the price of U. S. and Fisk casings is the same, tube prices vary by approximately 50 cents, the difference in each case being in favor of the U. S. tubes.

GILBERT-REPUBLIC ON CALENDAR

Fight Over Pickard Rim Due for Trial—Claim and Counter Claim and Spirited Answers to Both.

Although it is nearly ten months since Justice Blanchard, sitting in the New York Supreme Court, signed an attachment in favor of Joseph M. Gilbert, of New York, against the Republic Rubber Co., of Youngstown, O., and its New York branch, it appears that the merits of the dispute never have been aired, and that the transfer of the suit to the Federal courts will give the warring parties the first chance to argue the case before a tribunal. The transfer took place upon repeated request of the Republic Rubber Co., which claimed immunity from state court jurisdiction on account of its being a foreign corporation, which request finally was granted late last fall, and the case is now on the April trial calendar.

As will be recalled, the action hinges upon a patent covering a detachable rim, No. 771,445, issued to Orson L. Pickard, October 4, 1904, and reissued November 13, 1906, as Reissue No. 12,450, which patents, after considerable effort to market them, were purchased by the Republic company for a cash consideration and a royalty of 1¼ per cent. on the total sales. As told in the Motor World of June 15, 1911, Pickard claims he had a hard time trying to make the Republic company live up to its contract, and, lacking the means to engage in an expensive patent litigation, transferred all his rights and claims to Joseph M. Gilbert, general manager of the United States Tire Co., for a valuable consideration. Gilbert thereupon instituted suit for $8,500, which sum represents the accrued royalties for four years plus interest.

In its reply to these charges, the Republic Rubber Co. admits that it made the contract with Pickard, and that it did not pay the royalties agreed upon, but charges that Pickard had agreed not to transfer his patent rights to any other firm or corporation; that he did transfer such rights to Gilbert, an officer of a competitive concern, and that he thereby violated his contract. This, in effect, it is claimed, released the Republic company from further obligations. In addition, the answer charges that this transfer of Pickard's rights resulted in considerable loss and damage to the defendant's business, for which loss it files a counter claim for $10,000.

In terse, clear language, the reply of Joseph M. Gilbert, who now is general manager of the United States Tire Co., to the charges contained in the defendant's counter claim, states that he notified the Republic company of his acquisition of the Pickard rights and asked for the royalties due; being refused, he then proceeded to employ the patented article, as he was entitled to do according to his agreement with the patentee. He emphatically denies using the patented rim previous to his acquisition of the claim and rights of the patentee.

$110,000 Suit Is Settled Out of Court.

"If it ever goes to trial" was the preface of the Motor World on January 25 last, in relating the filing of a $110,000 suit in the New York Supreme Court by Thomas Salisbury Huff and Charles E. Coryell against the Imperial Storage Battery Co., and, as events proved, the case never did come to trial, the warring parties electing to adjust their differences out of court. In their complaint Huff and Coryell charged the Imperial Storage Co. with withholding their broker's commissions and bonus for arranging to sell Imperial stock. The company's president filed a vigorous, none-too-complimentary reply to these charges, and, probably to avoid an airing of these charges and countercharges in public, the suit was amicably settled.

To Call Conference of Sales Managers.

In order that they may compare notes, exchange opinions and otherwise "reason together," the sales managers of the companies comprising the Automobile Board of Trade will be called together for a meeting in New York, which will occur after the rush of spring business is over, probably in June. The decision to do so was reached at the general quarterly meeting of the Board of Trade in New York on Thursday last. The meeting of the sales managers will be directed by the Board of Trade's trade committee, which comprises H. O. Smith, chairman; E. R. Benson, W. E. Metzger, C. W. Churchill and W. T. White.

Larger Factory for the Saxon Lamp.

The Saxon Mfg. Co., which several months since was organized in Toledo, under the laws of Ohio, to manufacture lamps and horns, has leased a five-story brick factory building on Cherry street, Toledo. It will take possession in the early summer. The new structure will afford about five times as much room as the present plant occupied by the Saxon company. Herman Saxon, the president of the concern, formerly was the head of the Saxon Lamp Co., of New York, which went into bankruptcy at about the same time that the Ohio corporation was organized.

May Be Fined for Failure to File Reports.

For failure to file corporation reports for the year ending December 31, 1910, Cimiotti Bros., New York agents for Pullman cars, and the Hotchkiss Import Co., of New York City, have been sued by the United States government for $10,000 each. The sum represents the maximum fine which is provided for in the corporation laws for failure to file the annual report.

WEED TIRE CHAIN WINS IN WISCONSIN

"'Anchors' a Subterfuge to Evade Patent," Says Court—Non-Creeping Principle Again the Issue at Stake.

Having evolved a non-creeping tire chain, which the Channon counsel held did not infringe the Parsons patent, the H. Channon Co., of Chicago, in no uncertain language, hurled defiance at the Weed Chain Tire Grip Co., and as a result the Weed company accepted the challenge; but instead of acting directly against the Channon company, the Weed interests selected and proceeded against a Wisconsin customer of the Channon company for infringement of the Parsons patent, and last week obtained the preliminary injunction prayed for.

Herbert R. Johnson and Alexander P. Schellin, who constitute the Wisconsin firm and who had purchased parts from the Channon company and employed them in what they styled the Pioneer Chain Grip, were the nominal defendants. The actual defense, however, was undertaken by the Channon company, and as a test case the merits of the patent and of the articles involved were exhaustively gone into before Judge Sanborn, in the United States District Court for the Eastern District of Wisconsin, to the advantage of the Weed company.

The Pioneer grip is provided with an extra piece of chain fastened to one of the side members and with a snap hook on the loose end, attached to which piece of chain was a notice directing the purchaser to use the extra piece of chain in anchoring the grip to the wheel so as to prevent creeping, the Channon company having long contended that the Parsons patent applied only to creeping chains, while the Weed company maintained that it applied to non-skid tire chains of every character.

In the case before Judge Sanborn, the Weed interests brought testimony to show that the anchors involved were adopted solely in an attempt to evade the Parsons patent, and were abandoned when apparent need for the anchors for such purpose ceased. Other testimony was produced to the effect that the Channon company itself, during the past winter, had been shipping its Gripwell chains into Canada without providing them with anchors.

The Channon company filed numerous affidavits from users of their parts to show that the latter had adopted the anchors in good faith, and with the intention and belief that they would be used to prevent creeping.

In granting the preliminary injunction, however, Judge Sanborn said that, without deciding whether the defendant's position in this regard is well taken, he "was thoroughly convinced that he never had any such intention," adding that the "furnishing of the anchors was simply a subterfuge to evade the right of the patent owners."

K-W Ignition Sues for Consigned Goods.

On Tuesday, the 2nd inst., United States Marshall William Henkel attached a number of magnetos, coils and other ignition devices belonging the K-W Ignition Co., of Cleveland, O., which devices had been placed on consignment with Arthur H. Green, of 1686 Broadway, New York City. The attachment grew out of a suit which soon will come to trial in the United States District Court for the Southern District of New York. According to the complaint, the K-W Ignition Co., between January 12, 1911, and November 18, 1911, shipped on consignment to Green $4,542.87 worth of goods, of which $282 worth since has been sold. It is alleged that the money is being withheld by Green, and the K-W Ignition Co. asks that he be required to turn over the $282 in cash, to return the remainder of the goods, valued at $4,085, and to pay $500 damages for unwarranted detention of the goods.

Flanders Adds an Electric at $2,250.

The Flanders Mfg. Co. has added a new model to its line of electric cars. It differs from the older ones in price and, mechanically, chiefly in that it employs 30 cells instead of 24, which necessitates the distribution of the battery, 10 of the cells now being carried in the rear. This change required a slight alteration in the rear of the Colonial body design, which it is believed adds not a little to its appearance. The wheelbase has been increased by three inches; the motor is larger and a different and better controller, mounted on top of the steering column, now is employed. The price of the new model is $2,250, or $475 more than the old one.

To Produce Meeder's Motor Starter.

The Council Bluffs Auto Starter Co., capitalized at $100,000, has been organized in Council Bluffs, Iowa, to manufacture and market the engine starter invented by H. L. Meeder, who has been elected president of the new company. The other officers are: C. M. Nicholson, vice-president; George S. Wright, secretary, and C. R. Hannan, Jr., treasurer, who, with H. Doolittle, George Van Brunt and B. M. Sargent, constitute the board of directors.

Broga Fasteners on an Agency Basis.

The Broga Automatic Fastener Co., of Syracuse, N. Y., which manufactures an automobile curtain fastener of uncommon merit, and which heretofore has marketed its product through distributors located in a limited number of the larger cities, has altered its selling policy and hereafter will sell its goods on an agency basis. Such representatives are being established in all cities and towns which appear to justify such appointments.

ENGINE STARTER PATENT BOBS UP

Issued in 1895 and Soon to Expire But Inventor "Serves Notice" on Trade—How It May Apply.

That patents involving automatic engine starters were due for an airing has been almost a matter of course. Indeed, it is known that during recent months several patents have been subjected to the legal microscope in the effort to discover basic principles on which proceedings for infringement might be instituted.

The first of these patents to be brought to bear on the trade, and which promises to engage the attention of the courts, is that of Gilson W. Roth, of Indianapolis, whose patent, No. 549,213, dates back to November 5, 1895, and which, therefore, has left in it but seven months of life. Apparently on the principle that while there is life there is hope, Roth's attorneys have served notice of infringement on all persons who produce self-starters of whatever sort, notifying them that they are infringing Roth's patent and requesting that they "at once desist from further infringement and to account for and to pay over to them all profits, gains and advantages which they have derived from such manufacture and sale, as well as all damages which Roth has suffered by reason of such acts."

So far as is known, none of those on whom the notice has been served has become unduly alarmed, and none is making undue haste to "pay over his profits, gains," etc. They are calmly awaiting the suits which Roth's lawyers threaten to institute.

Roth's patent specifically covers a "gas engine igniter" applied to two-cylinder opposed motors, and assuredly was not designed with motor cars in view. Its possible merit, so far as they are concerned, is confined to a clause in the patent which provides for a "means of causing a spark when the engine is not running." In the light of present-day practice, however, the Roth igniter is almost archaic, although the apparatus for producing the spark when the motor is inoperative is not without ingenuity.

The device consists of nothing more complicated than a forked electrode carried on a rotatable shaft, which passes through an insulating bushing to the outside of the cylinder, where a hard rubber handle is provided for convenience in turning the shaft. Two flexible electrodes pass through the head of the cylinder and are so placed with relation to the forked electrode that one branch of the latter comes in contact with each of them when the rubber handle is turned slightly in a clockwise direction. Naturally, when the handle is returned to its former position, the break between the forked electrode and the flexible electrodes

Digitized by Google

is accompanied by a spark capable of igniting the explosive mixture.

Roth's patent comprises six claims, only three of which are cited in the notice which his lawyers have served on engine starter manufacturers. They are as follows:

1. In a gas or gasolene engine, the combination with two or more cylinders, of a piston in each cylinder, the crank shaft connected with said pistons, valves controlling the supply of explosive material to each cylinder and also controlling the exhaust, a vertical shaft operating from the crank shaft, operatively connected with said supply and exhaust valves, and devices for igniting the charge of explosive materials in each of the cylinders successively, and a circuit breaker, operated by a cam for each set of cylinders to connect the circuit to cause a spark in each of the cylinders at the proper time and means for procuring a spark when the engine is not running, substantially as described.

2. In combination, the cylinder, the stationary electrodes secured in the head thereof, the reciprocating piston carrying an electrode to contact and break contact with said stationary electrodes to form a spark and supplemental means for forming a spark when the piston is inactive, substantially as described.

6. In a gas engine having two pairs of cylinders, the electrodes secured in the heads of each cylinder, the common wires connecting the electrodes of each pair of cylinders, the independent contact, the circuit through each pair of cylinders, substantially as described.

To Build Electric Cars in Chicago.

Backed, it is stated, by millions of dollars, the Chicago Electric Motor Car Co. has been formed in Chicago, Ill., for the production of what will be styled the "Chicago Electrics." It already has secured a plant at 35th and Morgan street. Frederick J. Newman, who for many years was associated with the Woods Motor Vehicle Co., Chicago, is president of the new concern, Alfred J. Leopold is secretary and Albert Meyer is treasurer. C. J. Blakeslee, who was a member of the Woods engineering staff, is the engineer of the new company, which will build a shaft-driven, Firestone-tired car, having a wheel base of 96 inches and of three, four and five passenger capacity, the bodies being of all aluminum. A new Westinghouse motor, which it is claimed will deliver 25 per cent. more power and weigh 50 per cent. less than other motors, will be employed. Deliveries of the car will begin about September 1.

Hearst to Erect an "Automobile Building."

William Randolph Hearst, the "philanthropist" and friend of the common "peepul," who, through his numerous publications in New York, Boston, Chicago, Los Angeles, San Francisco and elsewhere, has reached into the automobile trade, has laid plans to reach the same industry from another angle. He is about to erect a four-story marble-front building in New York, on the block bounded by Columbus Circle, Central Park West, Broadway and 61st street, which will contain 19 stores on the ground floor, and which will be designed especially for automobile occupancy.

RUBBER GOODS'S PROSPEROUS YEAR

Slight Decline in Sales, Large Increase in Profits Due to Tire Sales—Total Business, $35,188,295.

Despite the fact that its net sales during the twelve months ending December 31st last showed a decrease of $600,000, the year was the most satisfactory one in the history of the Rubber Goods Mfg. Co., according to the annual report rendered by its president, Elisha S. Williams, which bears date April 11th but which was circulated in advance of the annual meeting in Jersey City on that day.

The apparent illogic of the situation is explained by the fact that though the sales decreased slightly the profits for the year increased substantially—from $2,122,247.62 in 1910, to $3,500,997.23 in 1911. In 1910, the net sales amounted to $35,188,295, which was an increase of practically $10,000,000 over the sales of the previous year. Last year the total sales attained a value of $34,587,269, which slight decrease President Williams attributes to the lower selling prices which prevailed during 1911, while the profit is accounted for by the great increase in the quantity of the manufactured goods sold.

Incidentally the increase is due chiefly to the demand for automobile and other tires, the sale of mechanical and miscellaneous goods, especially those used by railroads, having fallen off. President Williams also remarks the benefits that followed the amalgamation, in March, 1911, of the selling departments of the four factories which are controlled by the Rubber Goods Mfg. Co., i. e., Hartford, Morgan & Wright, G & J and Continental-Revere. Despite the great expense which the change involved, the policy, he states, "has proven successful and great benefits should be derived therefrom in the future."

The officers of the Rubber Goods company for 1911-1912, are as follows: Elisha S. Williams, president; Lester Leland and Charles A. Hunter, vice-presidents; Edward J. Hathorne, treasurer; Samuel Morris, secretary, and John D. Carberry, assistant secretary and assistant treasurer. The directors are: Anthony N. Brady, Samuel P. Colt, Frank W. Eddy, James B. Ford, Ernest Hopkinson, Charles A. Hunter, Arthur L. Kelly, Lester Leland, Homer E. Sawyer and Elisha S. Williams.

The financial interest of the big holding company is disclosed in detail by the treasurer's report, as follows:

CONSOLIDATED GENERAL BALANCE SHEET

Assets.

Property, Plants and Investments		$26,602,908.44
Patents and Trademarks		1,570,577.89
Inventories, Manufactured Goods and Materials	$10,495,130.68	
Cash	2,043,593.70	
Bills and Accounts Receivable	6,915,644.60	19,454,368.98
Stock Owned in General Rubber Co.	1,666,700.00	
Securities owned	383,450.00	2,050,150.00
Miscellaneous Assets		292,136.03
Total Assets		$49,970,141.34

Liabilities.

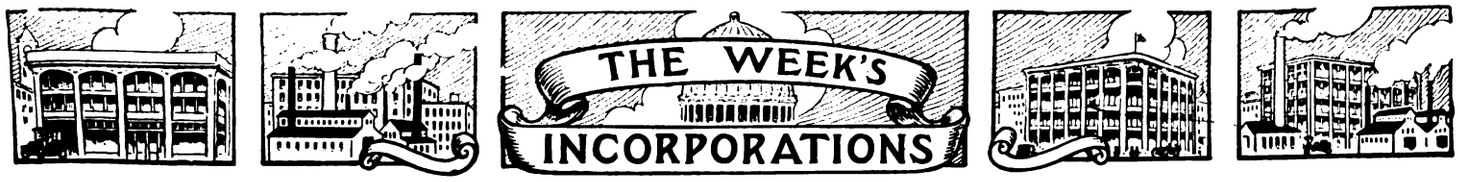
Capital Stock (Prefd.)	$10,351,400.00	
Capital Stock (Com.)	16,941,700.00	$27,293,100.00
Bonds of Mechanical Rubber Co. and N. Y. Belting & Packing Co. (less amt. owned)	974,510.00	
Sinking Fund Cash in hands of Trustee	302,220.94	672,289.06
Reserve for Redemption of Bonds		454,326.12
Bills and Accounts Payable		7,164,541.31
Accounts Payable to General Rubber Co.		3,591,355.13
Reserve for Federal Excise Tax		34,433.81
Fixed Surplus (Subsidiary Companies)		2,499,218.65
Surplus		8,260,877.26
Total Liabilities		$49,970,141.34

Of the above "Assets" and "Surplus" $185,234.21 represents the ratable interest therein of minority stockholders in Subsidiary Companies of the Rubber Goods Manufacturing Company.
Contingent liabilities for certain guarantees, which are offset by corresponding contingent assets, are not included.

Consolidated Summary of Income and Profit and Loss.

Net Sales		$34,587,269.15
Earnings		3,607,895.87
Income from Investments		100,000.00
		$3,707,895.87
Less:		
Expenses of Home Office		206,898.64
Net Profits		$3,500,997.23
*Dividends	$2,159,761.93	
Depreciation on Patents and Trademarks	46,543.43	2,206,305.36
		$1,294,691.87
Transferred from Reserves to Surplus		407,653.72
Surplus for the Period		$1,702,345.59
Surplus and Working Capital January 1, 1911		6,558,531.67
Surplus and Working Capital, December 31, 1911		$8,260,877.26

*Includes $79,827.93 paid minority interests in two Subsidiary Companies.



Fisk Presses Three Claims Against Jobber.

That the Automobile Tire Co., of 1625 Broadway, New York City, failed to meet two promissory notes for $3,000 each, of two and three months' duration, respectively, which were issued to the Fisk Rubber Co. for value received, is the charge made in the suit of the Fisk Co. against the Automobile Tire Co., which is on the current calendar in the United States District Court for the Southern District of New York. The Fisk Rubber Co. furthermore charges that $3,272.95 is due on a bill of goods, which in total amounted to $54,029.95 and which was contracted between September, 1910, and July, 1911. All these claims are merged in one action, in which the Fisk Co. sues for $9,305.45 plus interest and costs. The Automobile Tire Co. disputes the claim and by its refusal to pay brought on the legal proceedings in the Federal court.

To Make Wheel Parts in Albion.

Mark Merriman, vice-president of the Hayes Wheel Co., of Jackson, Mich., has purchased a factory building in Albion, in the same State, and will engage in wheel manufacture on his own account. He will devote himself more particularly to the production of wheel parts than of complete wheels.

Utica, N. Y.—Xargil Kerosene Engine Co., under New York laws, with $100,000 capital; to manufacture internal combustion motors. Corporators—B. F. Gilbert, G. A. Frisbie, J. A. Xargil, all of Utica.

Greenwich, Conn.—Porto Rico Motor Co., under Connecticut laws, with $150,000 capital; to deal in motors. Corporators—Milton A. Mills, Jr., Loring J. Whiteside and Edward J. Ryan, all of New York City.

Wilmington, Del.—Jiffy Auto Curtain Co., under Delaware laws, with $100,000 capital; to manufacture automobile tops and curtains. Corporators—E. E. McWhiney, W. J. Maloney, N. B. Coffin, all of Wilmington.

Rochester, N. Y.—Pembroke Manufacturing Co., under New York laws, with $50,000 capital; to manufacture automobile supplies and accessories. Corporators—C. J. Pembroke, W. P. Pembroke and W. J. Fellows.

Dover, Del.—Moon Motor Car Co., of Philadelphia, under Delaware laws, with $100,000 capital; to deal in automobiles. Corporators—L. T. Edwards, Philadelphia; E. A. Edwards and J. M. Frere, Wilmington.

New York, N. Y.—Charles H. Tucker Co., under New York laws, with $100,000 capital; to manufacture tires, tubes, etc. Corporators—Charles H. Tucker, Edward R. Wood and Henry W. Solomons, all of 1974 Broadway.

Los Angeles, Cal.—Los Angeles Motor Car Manufacturing Co., under California laws, with $20,000 capital; to deal in motor cars. Corporators—J. B. Morrow, Paul Brown, Jr., O. B. Hutchings, J. R. Fouch, J. Murphy.

Riverhead, N. Y.—Vail-Campbell Co., under New York laws, with $5,000 capital; to conduct a general automobile repair business. Corporators—Hilaire E. Campbell, Raymond H. Vail, Katherine Campbell, all of Riverhead.

Dayton, Ohio—Dayton Auto Delivery Co., under Ohio laws, with 125,000 capital; to operate a general transfer business. Corporators—John C. Hamilton, Sol Flatau, W. H. Spickler, Dr. H. C. McClelland and E. V. Menier.

Camden, N. J.—Ceyton-Filles Co., under New Jersey laws, with $3,000 capital; to manufacture automobiles. Corporators—Howard L. Merrick, John A. Kinney, William Williams, Thomas W. Shora, all of Collingswood.

OLD TRADESMEN IN NEW PLACES

Some Resign and Many Climb to Higher Positions—Transfers Reported from All Parts of the Country.

P. J. Tieber has been appointed manager of the Lozier branch in Cleveland. He succeeds W. H. Kirkpatrick, resigned.

E. N. Sanders, assistant manager of the Moon Motor Car Co.'s branch in Chicago, has been promoted to the management of that establishment.

George L. Sullivan, one of the American Locomotive Co.'s traveling staff has been promoted to the post of supervisor. His particular supervision will extend to the Alco branch houses in Chicago, Boston and Montreal.

Ralph W. Keeler has been appointed general manager for the Miller Car Co., which recently was organized in Detroit to manufacture the Miller car. Previously Keeler was identified with the Hupmobile sales organization.

L. E. Whitmore has been appointed sales manager for the Franklin Automobile Co. for the States of Louisiana, Arkansas, Texas, Oklahoma, Arizona and New Mexico. He will make his headquarters in Dallas, Texas.

R. H. Schmittdiel has been appointed assistant sales manager for the Empire Automobile Co., of Indianapolis. He has had ripe experience, having been connected with the sales staffs of the Brush and Regal establishments for several years.

W. J. St. Onge, formerly with the Dean Electric Co., of Elyria, O., has been appointed advertising manager for the Anderson Carriage Co., of Detroit, Mich. He succeeds Hal Smith, who resigned to join the electric vehicle staff of the General Motors Company.

Charles W. Garratt has been elected secretary and treasurer of the Federal Motor Truck Co., of Detroit. For twelve years Garratt was associated with the American Radiator Co., and later served as assistant treasurer and as a director of the United States Heating Co.

A. L. Tisch, of New York, has been appointed advertising manager for the Haynes Automobile Co., of Kokomo, Ind. In addition to his advertising experience, Tisch has the advantage of actual mechanical training, which will serve him to good purpose in his new position. He succeeds A. A. Franklin.

F. A. Babcock, who formerly was connected with the Franklin Automobile Co, has been appointed Northwestern sales manager for the R-C-H Corporation, of Detroit. He will have his office in Minneapolis, and his territory will comprise Minnesota, North Dakota, South Dakota, Montana and Northern Wisconsin.

After having been identified with the automobile business almost since its inception, R. T. Houk, who for the past year has been sales manager for the Stoddard-Dayton division of the United States Motor Co., has resigned that office to engage in a wholly different business. He will become general manager of a large mill in Ohio, of which he has been a director for several years.

W. H. Cameron, former chief engineer for the Willys-Overland Co., has engaged with the Flanders Mfg. Co., of Pontiac, Mich. He will have to do chiefly with the Flanders gear work but will also have a hand in the designing of Flanders motorcycles and electric cars. Despite rumors to the contrary, Cameron has nothing to do with the Universal Truck Co., of Detroit.

Tom O. Jones, one of the three men who constituted the Hupmobile globe-girdling export expedition, has been appointed assistant export manager for the R-C-H Corporation, of Detroit. Jones is a former newspaper man, and his training in that field, together with experience gained during the globe-girdling feat, will serve him well in prosecuting his new duties.

W. J. Teagan, who for twelve years has handled New England territory for the Goodyear Tire & Rubber Co., of Akron, Ohio, and who latterly has served as manager of its Boston branch, has been promoted to the post of district manager for New England. The vacancy created by Teagan's elevation has been filled by the appointment of C. M. McCreery, formerly with the Goodyear factory in Akron.

Following the policy adopted by the Franklin Automobile Co. of locating district sales managers in the particular territory in which their work lies, L. R. Gindrat has been appointed sales manager for that company's Southern district, with headquarters at Atlanta, Ga. The territory which he will supervise includes North Carolina, South Carolina, Georgia, Alabama and Florida. Previously, Gindrat was manager of the Franklin branch in Baltimore.

Chicago Trade Wants Fall Truck Show.

Among other plans, that super-active organization, the Chicago Automobile Trade Association is anxious to promote a commercial vehicle show in the Coliseum in the fall of the present year, and has taken steps in that direction. Whether or not the event ever will come to pass is in doubt, however, for though formal application for a sanction has been made to the National Association of Automobile Manufacturers, at the New York headquarters it is stated that it is unlikely that a sanction will be issued for such a purely local affair.

Newark Tire Plant Moved to Buffalo.

The entire equipment of the Newark Rubber Co., of Newark, N. J., has been purchased by the Frontier Tire and Rubber Co., of Buffalo. When it is installed, the added machinery will, of course, greatly increase the facilities of the company.

Digitized by Google

The Klemm Auto Co., of Davenport, Ia., has changed its name to Union Motor Co.

Frank Reckenthaler has taken over the garage formerly operated by Bullock & Bauman, at Cushing, Iowa.

W. A. Sawyer has purchased the Holloway Garage, in Bucyrus, Ohio. He will handle several popular priced cars.

Q. J. Smith, who was the Ford agent at Warren, Pa., has sold his agency business to the Wilson Taxicab Co. of the same city.

Under the style Collins Auto Repair Co. a new concern has "opened up" in Palatka, Fla., at 712 Lemon street. Elmer Collins is in charge.

The Probey Carriage Co., 1230 Wisconsin avenue, Washington, D. C., has taken on automobiles. It is handling the Michigan and Detroiter cars.

A branch of the United States Tire Co. was opened on April 1 at 406 West Ninth street, Des Moines, Iowa. W. H. Mesenbrink is the manager.

The Beehler & Odgen Automobile Co. is building a big salesroom and service building on Lexington street. Baltimore, Md. Krit cars are handled.

Clover & Allen have inaugurated a garage and repair business at 231 South Eleventh street, Lincoln, Neb. They have the agency for the Inter-State line.

C. G. Freeberg, owner of the Commercial Hotel at Decorah, Ia., has added automobiles to his hostelry business and taken the agency for Nyberg cars.

The Acorn Tire & Supply Co. has established itself at 25 William street, Newark, N. J. R. D. Crocker, president of the company, is in active charge of it.

Howard B. Hewitt and Floyd Pease have opened a salesroom and repair shop in North Yakima, Wash., where they will handle Reo and Apperson cars.

Judge F. W. Jenkins, of Eau Claire, Wis., has leased the premises 124 East Central street and opened a public garage. It will be managed by Peter Pangbourn.

Rownd's Garage, in Grand Island, Neb., has changed hands. J. H. Jarvis and O. J. Bauder, the new owners, will operate under the style Jarvis-Bauder Auto Co

Peter P. and T. K. Swanson have opened a garage and salesroom at 2101 Monroe street, Spokane, Wash. They have the distributing agency for Sullivan commercial vehicles.

Charles J. Gray, who has a bicycle store and cutlery business in Gloucester, Mass., has branched into the automobile line. He is building a garage large enough to accommodate 100 cars.

Fred Clasby and George Hoffman have formed a partnership and opened a repair shop on Ninth street, Marysville, Kan. They will do business under the style of Clasby & Hoffman.

The Market Garage & Machine Co. is the style of a new company which is building a garage at 1035 Market street, Parkersburg, W. Va. L. G. Meed and E. W. St. Clair are interested in the company.

The Colorado Rubber Co., of Denver, is erecting a modern four-story fireproof building at 1825-1831 Lawrence street, which will be ready for occupancy July 15th. It wil lrepresent a cost of $52,000.

A factory branch and service deparement is being erected for the Peerless Motor Co. of New England, distributors of Peerless cars, at 773 Broad street, Providence, R. I. The management will be in the hands of J. W. Breeze.

Herman Tietgen has bought the Monroe Garage, at Monroe street and Sharp avenue, Spokane, Wash., from its former owners, I. N. Benson and J. B. Ballard. He formerly was manager of the Lake City Garage at Coeur d'Alene, Idaho.

The Stoddard-Dayton Motor Co. of Hartford has been incorporated under Connecticut laws, for the purpose of dealing in Stoddard-Dayton cars. Walter D. King, of Hartford, is president, and Wells H. Wetherell secretary and treasurer.

Departing from the automobile district, the W. M. Laird Co., Pittsburgh distributor of Pullman cars, has opened a salesroom in Liberty avenue, which is in the downtown district. It is stated that other companies soon will follow the example.

The Goodyear Tire & Rubber Co. has leased the building now being erected at 1016 14th street, Washington, D. C., and will take possession about July 1st. At that time the Goodyear branch, of course, will remove from its persent location, 1026 Connecticut avenue.

The Empire Tire Repair Co., of Spokane, Wash., has been reorganized and will do business under the incorporated name Empire Tire Repair and Supply Co., at 1007 First avenue. M. W. Bean, J. G. Kilmer and H. E. Frazier are the men who compose the company.

H. W. Marshall has disposed of his interests and retired from the Marshall-Parsons Co., of Washington, D. C., agent for the S. G. V. car. The business will be continued by Frederick Parsons. Marshall has removed from Washington and gone into business at Fort Wayne, Ind.

Prosperity having smiled on him, H. G. Raymond is building a new garage in Fort Wayne, Ind., where he will display Imperial and R-C-H gasolene cars and Waverley electrics. The structure will be one story high, covering 7,680 square feet, of fireproof steel and concrete construction.

The R. & L. Co., of New York, metropolitan distributor of Garford cars and trucks, has established a branch in Newark, N. J., at 987 Broad street. It is in charge of Jacob A. Rainier. Ultimately it is the purpose of the R. & L. Co. to erect a four-story sales and service building in Newark.

At a total cost of about $60,000, the Pittsburgh-Chalmers Co., distributor of Chalmers cars in the Smoky City, is preparing to erect a building on Louisa street, opposite the entrance to Forbes Field, which will be used as display rooms, business offices and service department. A. C. Simler is president of the company.

Edward L. Graves, formerly with the Studebaker Corporation and the American Motor Co., and Otto R. Michel, of Sandusky, Ohio, have formed the Alco Motor Car Co., in Cleveland, where they will handle the Alco cars and trucks. Graves is president and general manager of the company and Michel vice-president and treasurer.

The partnership of Lee Arris and Mrs. Adele B. Dee, who operated the Pacific Garage in Turlock, Cal., is to be dissolved upon the petition of Mrs. Dee. In her application to the court she states that she fears that Arris will do bodily harm to her husband, and she asks that her partner be ordered to pay all outstanding debts of the firm and divide the remaining money with her.

The Dennis Motor Co., of Toledo, has been incorporated, under the laws of Ohio, with $25,000 capital stock, and has taken over the business of the Rambler Motor Sales Co. in that city, and thereby acquired the agency for the Rambler car, which will be handles in conjunction with Alcos, Cinos and Detroit electrics. The incorporators of the Dennis company are H. H. Dennis, G. W. Close, Allen E. Reid, R. S. Woodrow and John G. Meister.

Recent Losses by Fire.

Ogdensburg, N. Y.—Hannan & Henry's garage and 80 automobiles destroyed. Loss, $200,000.

Brooklyn, N. Y.—M. F. Marlborough's repair shop at 470 Clermont avenue, gutted. Loss, $20,000.

Hyannis, Mass.—Cape Cod Automobile Co.'s garage and 15 cars destroyed. Loss estimated at $25,000.

CONSPIRACY CHARGE IN CAB SUIT

Mysterious Stock Transactions Figure in Damage Suit—Receivership Asked for New York Taxicab Company.

That all was not as it should have been in the affairs of the New York Taxicab Co.—which concern not so long ago was absorbed by the Mason-Seaman Transportation Co., of New York City—is made evident by papers on file in the County Clerk's office entitled Mrs. James A. Bailey vs. New York Taxicab Co. According to the statement and affidavits submitted in the name of Mrs. Bailey, stock transactions of somewhat mysterious character took place, culminating in what the complaint terms a "conspiracy to defraud the public."

The particular transaction which is made the basis of the pending suit is one in which Mrs. Bailey is said to have been induced to buy 2,000 shares of the Taxicab Co. stock, paying therefor $10,000. Charles Mascart, who is made a co-defendant in the suit, is said to have been the dominating spirit in the scheme.

Mascart, who lives in Paris, is alleged to have originated the scheme under which Mrs. Bailey and other stockholders lost hundreds of thousands of dollars. The suit asks that Mascart be compelled to account for all the profits he made out of the scheme and seeks the appointment of a receiver for the New York Taxicab Co., with authority to dispose of the company's property and divide the assets among the stockholders.

The suit was brought in the name of Mrs. Bailey just before she died recently. Her brother and business manager, Joseph T. McCaddan, obtained an order in the Supreme Court to examine Mascart and the officers of the taxicab company concerning her allegations of a conspiracy to defraud. The order was served on Charles P. Callaghan as president of the New York Taxicab Co, but Supreme Court Justice Platzek vacated the order last week upon Callaghan's statement that he resigned last year.

In his petition for the order, McCaddan said that he would be able to prove by Mascart that the latter had formed a syndicate or pretended corporation which bought taxicabs at a low price and made secret profits to a large amount by selling the taxicabs to the New York Taxicab Co.

William P. Maloney, counsel for Mrs. Bailey, said in an affidavit that she bought her stock at $5 a share when the stock was first offered for sale, and the defendant corporations were fraudulently used to obtain moneys from the public. He said that after Mascart and others associated in the pool with him had sold hundreds of taxicabs at a great profit they caused a reorganization of the defendant companies for fraudulent purposes.

The complaint says that it was represented to the public that the New York Taxicab Co. owned more than 500 taxicabs and would make a profit of $945,000 a year out of them. It is alleged that Mascart and others have transferred 120 taxicabs to unidentified persons and that they have had a liquidator of the English corporation appointed to divert the assets from the stockholders of the New York corporation.

R. P. Henderson's Associates Made Known.

R. P. Henderson, president-to-be of the embryo Henderson Motor Car Co., of Indianapolis, has been able to prosecute his plans with more dispatch than at first was thought possible. They are already so well in hand that his new company probably will be incorporated early next week and be ready to take up the manufacture of the Henderson car early in July. The car itself will be well within the $1,200 class. It will mount a 35-horsepower motor, will have center control, left-hand drive, transmission on rear axle, a wheelbase of 116 inches, and 34-inch wheels. It will be built in two and five-passenger models, after designs by Charles S. Ricker, who will be the new company's designer and chief engineer.

R. P. Henderson's associates in the new venture also have been made known, and, contrary to earlier impressions, Charles P. Henderson, president of the Henderson Motor Sales Co., will be one of them. He will hold no office, however, and will devote his activities to the Cole company, whose general sales manager he will become when the merger is effected. At present he holds no stock in the Cole company, but it is likely that he shortly will become possessed of a block of it. R. P. Henderson's other associates in the new enterprise are L. Carter, of Jesup, Ga., president of the Henderson Motor Sales Co., who also is heavily interested in the Cole company and E. E. Rogers, of Indianapolis, who has been interested in the Sales company, but has no interest in the Cole corporation. R. P. Henderson himself will surrender his holdings in the Cole company to J. J. Cole, its president.

Hartford Garages Raise Their Rates.

Six of the principal garages in Hartford, Conn., have joined in announcing an increase in storage rates, which will date from May 1st. Thereafter the charge for open cars of 112-inch wheelbase, or less, will be $15 per month; for open cars of greater wheelbase, $20 per month. The charge for limousines and all other closed cars, regardless of their dimensions, will be advanced to $25 per month. The rates, of course, include washing and polishing.

Day Leases Factory at Detroit.

The Day Automobile Co., of Detroit, manufacturer of the Day utility car, a convertible vehicle, has leased for five years the factory building recently erected at 25 East Milwaukee avenue in that city. It is a two-story brick structure which will afford 20,000 square feet of floor space.

ALEXANDER STRAUS DIES AT DESK

Pioneer Tire Maker Suddenly Succumbs to Heart Disease—Prominent and Useful Parts He Played in Industry.

Alexander Straus, one of the genuine veterans of the tire industry, died suddenly on Tuesday last, the 9th inst., in the office of the Brander Auto Tire Co., 1987 Broadway, New York, with which concern he lately has been identified. He was dictating a letter when he fell from his chair, due to heart disease, with which he long had suffered.

Straus was born in Germany in 1852, and after graduating from the University of Frankfort he came to this country, soon thereafter engaging in the rubber business When the pneumatic tire first appeared, in 1889, it attracted his attention at once, and thereafter, with a few short intermissions, he applied himself assiduously to its perfection. He early invented a single-tube bicycle tire, which was produced by the New York Belting & Packing Co., and later developed other tires for the Newton Rubber Works, of Newton Upper Falls, Mass. He was in and out of the tire business on several occasions, and during the course of his activities assisted in founding both the Goodyear Tire & Rubber Co. and the Hardman Tire & Rubber Co., of which latter Joseph Straus, his eldest son, is president. His other two sons also are with the Hardman company.

Straus knew rubber to the last analysis, and, although in poor health during the last five years, it occupied most of his thoughts. Latterly he maintained that all present-day automobile tires are improperly constructed—that they should be made with a layer of rubber between each layer of fabric, and he had been developing a tire of that sort. It was also one of his favorite beliefs that the reason why one tire will give but 3,000 miles of service while another of the same brand will give 13,000 or 23,000 miles, is proof of the imperfect or otherwise defective construction of the short-lived tire. In addition to his three sons, Straus leaves a widow and two daughters.

To Enlarge Warner Plant in Beloit.

The Warner Instrument Co. has let contracts for the erection of an addition to its already large plant in Beloit, Wis. The new structure will be 100 x 100 feet and will be of the same brick and concrete construction as the present building.

Two More American Cars Enter England.

Two more American cars have entered the British market, the Metz and the Pathfinder. The former is handled by the British Lion Motor Car Co. and the latter has been put in the hands of C. M. Nankivel, both of London.

THE OVERLOADING AND OVERSPEEDING EVILS.

There never has been a time since the manufacture of motor trucks was commenced when truck manufacturers, as a class, did not more or less strenuously object to the overloading of their machines; and in this they naturally have been actively supported by the tire people. Within the last year or two, however, there has been more concerted action in this direction than ever before. Manufacturers of trucks and of tires are getting together and there is a strong tendency not merely to object to both overloading and overspeeding but to enforce such objections by the withdrawal of guarantees.

In the effort to eliminate, or at least to minimize, this evil, there is absolute necessity for co-operation that is consistent. For instance, what good does it do for a manufacturer to formulate rules if the sales agent does not back him up to the extent of enforcing those rules to the best of his ability? The very least an agent can do is to refrain from encouraging overloading and excessive speeds. Nevertheless it is an open secret that trucks placed on demonstration in charge of drivers employed by sales agents often are handled in a way that would arouse the unbounded indignation of the agent if the same thing were done by the purchaser of a truck under a guarantee. It is well known that demonstrating drivers have been paid bonuses in addition to their regular pay for tonnage hauled in excess of a stipulated amount, and that gross overloading and reckless speeding through the streets have resulted. The mere fact that a new truck under the care of an expert mechanic will stand up and make records that may be the direct cause of the sale of the machine does not justify the practice, however well it may speak for the capacity of the car for taking abuse. The prospective purchaser is led to believe that the machine is capable of doing more than he has any real right to expect, and he is placed in danger of having to pay a maintenance cost that he has not been led to anticipate; competing trucks that are normally loaded and carefully driven are placed in an unfair light and made to appear inferior, when such may not be the case; drivers who are to take charge after the conclusion of the demonstration period are encouraged to attempt similar stunts; and there is a strong element of danger to the public, as well as to the truck itself in its reckless career through city streets.

It is undeniable that when an agent knows he can take chances with a strong probability of pulling through safely, the temptation to try to make a competitor's machine appear at a disadvantage is extremely strong—especially if it is known that the competitor is likely to follow the same tactics. It is not fair competition, however; it is entirely contrary to the spirit of co-operation among truck makers themselves and between truck makers and the tire people that many fair minded concerns are now endeavoring to promote.

THE POPPET VALVE AS A GOOD OLD STAND-BY.

The poppet valve is an old, established institution, maligned in some cases, badly treated in most cases and poorly constructed in others. But all of this does not detract from the fact that it can be made, and is made, so that its operation is as "sweet" and as silent and as efficient as can be desired. That is to say, some poppet valve mechanisms approach the ideal in these respects. A great many fall short of it, however, though it apppears that if those manufacturers who seek to better their mechanisms would devote as much time and study and money to perfecting their poppet valves as the manufacturers of other types of valves find it absolutely necessary to devote to them in order to make them operate at all, they would have little difficulty in reducing noise and promoting efficiency. Some manufacturers really do give as much attention to their poppet valves as the workers in the other field devote to their slide or sleeve or rotary valves, and the fact that they reap benefits in proportion to their exertions should serve as a moral for others.

All of which is merely by way of pointing out that the poppet valve, when properly and painstakingly constructed, really is a good valve despite disparaging statements which have been made regarding it. There is no doubt that the poppet-valveless motor is a great thing; it marks a distinct advance in engineering practice, though it would seem that too soon have some engineers decided that something better than the poppet valve is necessary. But in all probability both types of engine have a long life before them despite the apparent imminence of the Deisel engine and other engines; neither type has reached the stage beyond which advance is impossible, and in the mean time it is meet that the poppet should receive at least at much attention as is being devoted to other types of valves in the hope of discovering something so infinitely better from every point of view that the poppet valve will be completely outclassed. In other words, it is well, first, actually to reach the limit in perfecting the poppet valve before finally turning too quickly or too sharply to other and newer mechanisms.

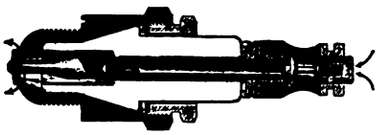
IMPROVING LOCAL CONDITIONS

Utica Dealers' Association Points the Way —Price-Cutting and Used Car Problems Simplified.



Although in existence but three months, the Utica Automobile Trades Association, of Utica, N. Y., appears to have accomplished far-reaching benefits. In the handling of even such aggravating problems as the used car, progress has been made. How the dealers are working together and what they have achieved was outlined at the annual banquet of the association last week in the address of its president, H. D. Gouse, who, among other things, said:

"First, the dealers have agreed to sell cars and equipment at list price. In addition to the price cutting on new cars, it was learned that a most deplorable condition existed respecting allowance on used cars. A committee was appointed by your association to consider and report as to fair allowances for used cars when taken in exchange. The work of investigating that matter and the establishing of a used car schedule involved an enormous amount of work on the committee. The committee, in arriving at their prices for used cars, based their report on the market value of the used car and recommended a schedule of prices at which the dealer could take in used cars and sell same without a loss, and at the same time make his legitimate profit on the new car which he sold. The report of the committee was adopted, and to-day each dealer is submitting the same price for a used car, which, as you well know, will prevent the owner from peddling around amongst the different dealers and getting each succeeding one to make him a greater allowance for his car, which, in the majority of the cases prior to the existence of the association, far exceeded the market value of the car.

"It must be appreciated by each of you that the success of an undertaking depends upon the loyal support and hearty co-operation of each one of its members, and I feel confident that such support and co-operation, which is essential, is given and will continue to be given by each member. In addition, it means hard work and plenty of it for each one of you. Another thing which appears to me to be necessary to success and the holding of the respect of the customer is that each one be treated rigidly alike. Almost every good car is represented in Utica by some one of its dealers, and, if you believe in the article which you are selling and it is priced right, there is no reason why you should not secure the list price. It is my contention, and I believe that each one of you agrees, that if you make a cut in the price or throw in a lot of extras, you are telling the customer that your asking price was too high. If a customer purchased a car at cut price, there was a question in his mind whether he had secured the lowest figure, and he left with less respect for you than had you not made the sale to him, because of your maintaining the price and treating each one alike."

Here's the "Air-Cooled" Spark Plug.

While the location of the spark plug on the engine is by no means standard, and it may be taken as axiomatic that where there are six manufacturers who prefer the central location of the plug because of the increased speed of flame propogation when plugs are so located, there are half a dozen who adhere to the custom of placing the plug in the valve pocket, where the cool gases from the inlet valve prevent undue temperatures. The advantages which obtain from both locations may be combined in a motor with centrally located plugs, provided the plugs used are of the "air-cooled" variety recently placed on the German market by Sorge & Sabeck, of Berlin; that is, if the statement of the makers can be taken as authentic. The plug, as shown by the accompanying illustration, while more or less of the conventional pattern,

GERMANY'S "AIR-COOLED" PLUG

incorporates somewhat of an innovation. The central metal spindle, which carries the current to the interior of the cylinder, is bored for about three-quarters of its length, and at the point where the hole terminates two small holes extend to the outside and provide an escape for the air which is drawn through the spindle. A check valve, housed in the brass cap of the plug, permits the free ingress of a certain amount of air on the suction stroke of the motor, but closes tightly to prevent the escape of the gases during the working stroke. The air so admitted, it is claimed, maintains the plug at a temperature much below that of the ordinary centrally located plug, and, moreover, tends to prevent the formation of carbon.

Mais Wants Pay for Wrecked Trucks.

Two suits, each for $4,000, have been filed in the Indiana Superior Court by the Mais Motor Truck Co., of Indianapolis, against the Cincinnati, Hamilton & Dayton Motor Railroad Co. and the Terre Haute, Indianapolis & Eastern Traction Co., respectively, the proceedings growing out of the destruction of Mais trucks by cars operated by the respective companies. In the suit against the railroad company, it is alleged that the flagman at the crossing signaled to the driver of the truck that all was safe when results proved otherwise. In the action against the traction company, the point involved is more finely drawn and more unusual. It appears that while driving in the trolley tracks the chauffeur of the Mais truck signaled to the motorman that he could not pull out of the tracks on account of their slippery condition. The trolley car, nevertheless, did not slacken its speed and the Mais truck was struck from behind and demolished, the driver escaping only by a nimble leap.

April 13, New York City—Annual Motor Truck parade under the auspices of the New York Motor Truck Club.

April 14, San Jose, Cal.—Track races promoted by J. Alex. Sloan.

April 29-May 4, Burlington, Vt.—Burlington Merchants' Protective Association's annual show in State Armory.

May 4, Santa Monica, Cal.—Santa Monica road race.

May 15-18, Chicago, Ill.—Chicago Motor Club's reliability run for commercial vehicles.

May 30, Indianapolis, Ind.—Five hundred miles International Sweepstakes race on the speedway.

May 30, Salem, N. H.—Rockingham Park track races.

June 8, Narberth, Pa.—Track races under the auspices of Quaker City Motor Club.

June 20, Chicago, Ill.—Chicago Motor Club's annual hill climbing contest on Algonquin Hill.

July 4-6, Old Orchard, Me.—Beach races under the auspices of the Old Orchard Automobile Association.

August 8-10, Galveston, Tex.—Beach races under the auspices of the Galveston Automobile Club.

August 23-24, Elgin, Ill.—Chicago Motor Club's national stock chassis road races.

September 2, Indianapolis, Ind.—Track races.

Melbourne in Market for Electrics.

The municipality of Melbourne, Australia, is inviting bids for three electric vehicles, which bids must be received on or before May 15th. One of the vehicles desired is a single-seated runabout, and the other two are wagons of the open body type, designed to carry loads of 1,000 and 2,000 pounds, respectively. In each case, the specifications call for the use of Edison storage batteries.

Leather Exports Show Slight Increase.

During February, 1912, $8,430 worth of leather for automobile use was exported from the United States, as compared with $7,902 worth in the same month of 1911. For the eight months ending February, the figures are $60,884 and $59,785, respectively, indicating that the trade in this line of merchandise practically is at a standstill.

MILWAUKEE GETS THE VANDERBILT

Also the Grand Prize Race—But Vanderbilt Must Be No Curtain-Raiser, Else Sanction May Be Denied.

Not New York, not Georgia, not even Texas, will furnish the setting for the eighth Vanderbilt Cup Race, for the state of Wisconsin, represented by the city of Milwaukee, which so suddenly entered the bidding, presented so many claims of superiority and real substance, that the classic event for the first time will go West. New York could not provide military protection, Georgia cried "enough," and Texas—that is Dallas, which sought the honor—could not offer attractions that compared with those presented by the Milwaukee Automobile Dealers' Association. As a result the executive board of the Motor Cups Holding Company, on Tuesday, the 9th inst., formally awarded both the Vanderbilt and the Grand Prize events to the Milwaukee promotors, the only stipulation for the running of the events being that the Vanderbilt race be run under sanction granted by the Contest Board of the A. A. A., while the Grand Prize race be run under sanction issued by the Automobile Club of America, which gave birth to the Grand Prize as a matter of spite at a time when the club was at loggerheads with the A. A. A.

The dates on which the two races will be run have not yet been definitely settled. It is understood, however, that the Vanderbilt will be decided on Labor Day, September 2nd, if it is possible. At any rate, the race will be run sometime between the 1st of September and the 5th of October. It is to be hoped that the Grand Prize race will not be run so close to the Vanderbilt race as to lessen the interest in the latter, as was the case last year at Savannah, Ga. Indeed, it is whispered that there is a chance that the Contest Board of the A. A. A. will refuse to sanction the event unless the dates of the two contests are far enough apart to insure individuality for the Vanderbilt race. Such action on the part of the Contest Board will prevent the Vanderbilt again assuming the role of a mere curtain-raiser for the one-time "spite race."

Oldfield, Reinstated, to Race Again.

Although he gave out that he was through with racing forever, Barney (Berna) Oldfield, like many another driver before him, has decided to "come back" after all now that his suspension by the American Automobile Association has been commuted to expire on April 30th. Negotiations have been completed between him and E. E. Hewlett, who is the Pacific Coast representative for Fiat cars, whereby he is to drive a 90-horsepower Fiat in the Santa Monica road races, which are scheduled for May 4th. Though it was rumored that he would drive a Benz, negotiations which were pending have fallen through, according to Jesse Froehlich, who states that though he wired Oldfield several times, no reply was received.

Technicality that May Curtail Reciprocity.

Despite the enactment of the reciprocity law by the New Jersey legislature, and the general belief that all bars had been let down, somebody in authority has found a way of continuing the irritation and bad feeling which has existed for so many years between New Jersey and its neighbors. While it is not disputed that it is no longer required that non-resident's cars be registered in New Jersey, and that their owners may drive them at their own sweet will, whoever it is that is bent on making trouble is seeking to set up the bar against professional chauffeurs. New York provides chauffeurs with a badge, which must be worn conspicuously, while New Jersey requires no badge whatever, and that technicality has been seized upon as being sufficient to require that New York chauceurs obtain Jersey licenses, and vice versa.

Although it is stated that New York's secretary of state is responsible for the ruling, at his branch office in New York Cty, where registration certificates and chauffeurs' licenses are issued, nothing whatsoever is known of such an order. Most of the indications point to the fact that J B. R. Smith, New Jersey's commissioner of motor vehicles, is the man who discovered the technicality and is seeking to make the most of it. His term has expired and he is merely holding over pending the appointment of his successor. The discovery of such a technicality as the one that has brought to bear is not inconsistent with his official attitude. He is a great handshaker, and knows how to put his arm on the other fellow's shoulder while professing cordiality, but not all of his actions have borne out this attitude.

Elgin's Association Elects Officers.

At the annual meeting of the Elgin National Road Race Association the following officers were elected: President, Harry D. Hemmens; vice-president, Theodore J. Schmitz; secretary, Wallace C. Wilson; treasurer, Philip Freiler; general manager, Fred W. Jenks.

The meeting took under consideration a proposed contract with the Chicago Motor Club to stage five events, including a free-for-all race, on the Elgin course on August 23rd and 24th, but it was decided that if upon investigation it should be determined that the free-for-all would in any way detract from the Elgin National Trophy race the event would be eliminated.

Ritchie Retires as N. Y. S. A. A. Secretary.

J. Arthur Ritchie, of Albany, secretary of the New York State Automobile Association, and one of its most earnest workers, has resigned that office. His successor has not yet been chosen.

HELD LIABLE FOR "CHECKED" CAR

New York Court Orders Innkeeper to Pay Damages to Motorist for Lost Car—Legal Points Involved.

Declaring that it is the duty of an innkeeper, who makes a business of "checking" the cars of his guests during the time of their stay in the inn or restaurant, to keep careful guard over them and to make good any damage or loss experienced while they are under his care, a jury in the Second District Municipal Court, of Brooklyn, N. Y., awarded $500 damages to Dr. A. S. Brinkerhoff, of Brooklyn. The sum represents the amount sued for the loss of the doctor's car while supposedly "checked" at Feltman's Brothers' cafe, on Coney Island.

According to the testimony submitted, Clifford Brinkerhoff, a son of the doctor, and three of his friends drove in the doctor's car to Feltman's. They put the machine into the parking space reserved by the management for the use of motorists and got from the uniformed attendant in charge a numbered check bearing the name of the Feltman establishment. An hour later, when they came to get the machine, it was gone. The car was found next day in a ditch in the Kingsbridge section of New York. The lamps, spare tires, speedometer, magneto and other movable attachments were missing. Other damage had been done, which brought the price of repairs and replacements to more than $700.

In order to avoid delays which would follow a suit in the Supreme Court, Dr. Brinkerhoff decided to bring it in the municipal court. He asked for the largest sum allowed in the lower civil court. Feltman Bros. refused to accept responsibility for the damage suffered, although they offered later to settle for $100, when they saw the doctor determined to sue.

It was contended by Dr. Brinkerhoff that the issuing of the numbered ticket, which was received from the uniformed attendant, made the Feltmans responsible for the car while it was in the parking space. Furthermore, the car was surrendered to whoever took it without any ticket being shown.

The Feltmans, in the trial of the suit, denied that the checking was under their control, and said that a man named George Davidson had it independent of them. It was testified, however, by others that the attendant wore a uniform marked with the name of Feltman's, and the ticket was so marked. The contention was raised by the defense that inasmuch as the parking space was maintained only as a convenience and no fee was charged, the restaurant folks could not be expected to be responsible for service rendered without compensation.

The jury was out only ten minutes, there seemingly being no doubt in its mind as to the responsibility of a man who "checks" cars—with or without direct pay.

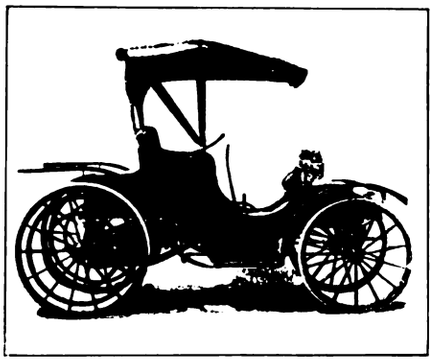
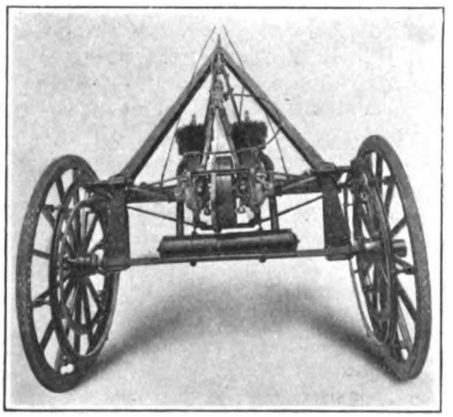
DURYEA IMPROVES HIS "ELECTA"



Veteran Manufacturer Further Simplifies His Already Simple Vehicle—Wherein He Found it Possible.

Having moved bag and baggage from Reading, Pa., to Saginaw, Mich., and having become settled in new quarters, Charles E. Duryea once more has started in earnest to produce Buggyauts, runabouts, motor accessories and novelties, this time under the firm name of the C. E. Duryea Co., successor to Chas. E. Duryea of the Pennsylvania city, and his latest product, which is styled the "Electa," though much like its immediate predecessor, is of even simpler construction. It already was very nearly the simplest vehicle of its kind extant, but despite that fact room for improvement has been found in several minor details, and by reason of several additions and alterations, its attractiveness has been considerably increased.

By way of permitting the greatest possible flexibility and the fullest benefit from the springs being obtained without danger of body distortion being transmitted to the mechanism of the vehicle, a triangular chassis frame has been adopted in place of the rectangular frame which heretofore has been used. The frame is attached to the front of the body by means of a ball and socket joint, and in addition to permitting a virtual three-point suspension of the body, allows lower suspension and thus increases the stability of the vehicle. As the front of the frame is carried by the body, which is supported by the springs, the motor and transmission gear is relieved from much of the shock incident to the passage of the vehicle over rough roads. Incidentally, the new arrangement furthers accessibility by permitting the body to be removed quite easily and quickly by the loosening of a few bolts.



The engine remains the same as it always has been, i. e., two air-cooled cylinders with the flywheel located between them, and the crankshaft serving also as the drive axle. The arrangement, which has always been a distinctive feature of Duryea cars and probably always will be, is shown quite clearly in the accompanying picture of the chassis. One of the new features is the incorporation of what is styled an easy starting device. In consists of a miniature pump by means of which the cylinders may be primed with gasolene, which, it is explained by the inventor, "makes an explosive mixture and also cuts the heavy cylinder oil, and makes the engine turn as freely on a cold day as when warm." Another slight change which has been made embraces the use of lighter inlet valves.

The transmission elements remain unchanged, the roller drive, which provides two speeds forward and reverse, being retained intact except that the method of attaching the rings to the wheels has been improved by the substitution of forged instead of partly cast fastenings. As heretofore, control and brake levers are placed in the center of the footboard, so that the vehicle may be operated from either side. In order to facilitate control, steering is

DURYEA'S LATEST—THE "ELECTA"

effected by means of a lever, which is hinged at the top, so that it may be swung over to either side. Practically the only other alteration which has been deemed advisable concerns the muffler, which has been enlarged in size and provided with

DURYEA'S "ELECTA" CHASSIS

a greater number of expansion chambers the better to silence the exhaust.

Hyatt Publishes a "Plant Book."

An unusually handsome piece of press work is the "plant book" published by the Hyatt Roller Bearing Co., of Newark, N. J., and Detroit, Mich.—so called because it is devoted to descriptions and illustrations of the plant at Newark, where the Hyatt roller bearings are made. The book—it really is more than a pamphlet—is of large size with an embossed, gold-lettered cover, and contains 52 pages. Beginning with a view of the complete plant, the various departments are illustrated by fine engravings, each occupying half of one of the large pages, with the descriptive matter printed below. The handsome offices and reception room, engineering offices, analytical and physical laboratories, testing department, power plant, stock room, the numerous machining departments and finishing rooms, tempering furnaces—all these and more are illustrated and described in a way that is highly creditable to the compilers. The "plant book" not only is interesting to read and look at, but it is well worth keeping. The Newark plant is the only factory of the Hyatt company, the Detroit offices being devoted to sales work and the arrangement of engineering matters in connection with the use of Hyatt bearings in motor cars.

"Peroxide Discovery" Is Exploded.

The British chemist who discovered that the addition of two ounces of "20-volume" peroxide of hydrogen to each pint of water used in an acetylene generator would increase the illuminating powers of the gas generated by about 50 per cent., has been "undone" and his theory being that the oxygen liberated from the peroxide materially aided combustion and hence the greater luminousity of the gas has been flouted. That there is absolutely no benefit derived from the practice has been demonstrated in a series of photometric tests conducted by Professor Vivian B. Lewes, chief superintending gas examiner of the City of London. Professor Lewes' tests were conducted in a very systematic manner, under varying conditions as to the types of generators used and the design of the burners and the pressure of the gas. Apart from the fact that the practice does not add light, Professor Norton declares that it is positively dangerous, as the mixture of oxygen and acetylene is very explosive.

Miller's Catalog a Near-Encyclopedia.

Attractive covers always have been features of the catalogs issued by Charles E. Miller, of 97-103 Reade street, New York, and the 1912 catalog, which just has been issued, is no exception to the rule. With a motor car in the foreground, flanked by a motorcycle and a motor boat and a couple of aeroplanes in the background, done in colors, the contents are vividly suggested. As usual, the Miller catalog is practically an encyclopedia of motor supplies; its 256 pages list an enormous variety of the things that pertain to motoring on land and water and in the air, from complete motors down to the smallest parts. Big as the catalog is, there is no difficulty in finding any particular article, a good index, which also is a Miller feature, making this easy.

Battery Gas That is Inflammable.

It not infrequently is denied that the fumes from a storage battery on charge are inflammable, but such is the case, and it is by no means safe to bring a naked flame near a cell that is "gasing" freely. Battery repair shops and charging stations usually are careful in this respect, knowing by practical experience that the gas can be ignited.

THE AMBULANCE MADE LUXURIOUS

Knox Brings Art and Ingenuity to Bear With Impressive Effect—Features of Most Modern Vehicle.

What appears to be the last word in ambulance construction comes from the Knox Automobile Co., of Springfield, Mass., whose long experience as builder of automobiles has been brought to bear on the problem of ambulance design, the result being the handsome car shown in the accompanying illustration.

The feature of the machine, which is built on a Knox 40-horsepower chassis with a wheel base of 134 inches, is the body. Strength, lightness and freedom from creaking when in motion being highly desirable, the framing was built up of rigidly braced ash, sheathed with one-piece sheet aluminum panels outside and with three-ply whitewood veneer within, the latter forming an unbroken and sanitary surface. The ash-wood floor is covered with linoleum. The body is divided into three compartments; the forward one for the driver, the second for the doctor's use, and the third, which of course is the largest, for patients. The doctor's compartment has a door on either side and is equipped with a seat, which is folded when not in use. This compartment opens directly into the rear of the body, there being no door between. This entrance is on one side, and back of the partition on the opposite side are two cots, one above the other, arranged so that they can be placed at any angle and also can be folded. Each cot slides smoothly into a metal frame, and under the lower one is a large locker for supplies. At each end of the cots, but on the opposite side of the car, are folding seats, and on the wall between them is a complete hot and cold water supply apparatus, with folding sink and a drain pipe which leads to the outside of the car. By lighting an alcohol lamp when the ambulance starts, water is heated while the car is on its way. A large vacuum bottle with rubber tube and faucet, and a rack of drinking cups are provided also, and there is a metal tray with antiseptic pad under the bottle.

Provision is made for an ample supply of fresh air by the use of three large ventilating shutters on each side under the roof, and there are windows in the doors and one in the wall opposite the cots, all of which can be opened. These afford ample light, and the white enamel finish of the interior is bright and sanitary. The double doors at the rear of the car open the full width of the body. At night illumination is furnished by an electric lighting installation, which includes a dynamo driven from the engine and a storage battery, kept charged by the dynamo, which furnishes current when the engine is idle.

NEW KNOX AMBULANCE WHICH AFFORDS UNUSUAL ACCOMMODATIONS

The tire equipment, which has much to do with the smooth running of the ambulance, consists of twin pneumatics in the rear and singles in front, all 38x5½ inches, and the springs, which are semi-elliptics, are long and easy. The exterior finish of the car is white with fine gold striping.

Improvement in Tungsten Filaments.

So severe are the conditions under which motor car electric lights are used that in order to have long life a lamp must possess exceptional qualities of resistance to vibration. Tungsten filament lamps have shown themselves well adapted to motor car work when properly made, and the "Mazda" lamps, which are now especially made for motor car work by the Federal Miniature Lamp Works, of the General Electric Co., of Cleveland, O., using a drawn wire filabent, are said to be unusually long lived and at the same time economical in the use of current. Tungsten filaments as originally constructed were decidedly weak and easily shaken to pieces, though highly efficient, but the drawn wire filaments now employed are much stronger and quite as economical.

SIMPLIFYING CHARGING OPERATIONS

Great Part the Mercury Arc Rectifier Has Played in Serving That End—Some Little-Understood Features.

When Peter Cooper Hewitt invented his mercury arc rectifier, safe to say he scarcely imagined the ultimate place it would make for itself in the world and the extent to which it would be used. Because it has been found cheaper and more economical to generate alterating current for transmission over long distances, and because direct current is used so extensively in operations for which alternating current cannot be used, the mercury arc rectifier slowly but surely is ousting other and more expensive methods of conversion. Just how important a place the mercury arc rectifier is destined eventually to occupy in commerce is revealed by the fact that recently perfected apparatus of this type is in use for the conversions of currents so heavy that heretofore it has been possible to handle them only through the medium of tremendously heavy and expensive rotary converters.

It is because of the inherent simplicity of the apparatus and its extraordinary efficiency that it has come into such general favor, one of its fields of usefulness being in the chargng of storage batteries. But even though the mercury arc rectifier is so extensively used and despite its extreme simplicity, there are few to whom its secrets, such as they are, are plain. The rectifier consists of a glass bulb from which the air has been exhausted and which contains an amount of mercury; the bulb, therefore, contains nothing but mercury and mercury vapor. Into the bulb the two terminals of a source of alternating current are inserted.

It has been found that at the negative electrode in the bulb there is a high reluctance to the passage of current, but there is practically no such reluctance at the positive electrode. Once the reluctance is broken down at the negative terminal, however, the passage of the current takes place with very little loss. Current cannot flow in the opposite direction, alternating current being current which flows alternately in one direction and then in the other, because the positive electrode then would become the negative electrode and would offer a high reluctance to the passage of the current.

One form of the rectifier is to use three positive electrodes, one for each phase of a three-phase circuit, and one negative electrode. As the three phases overlap, the negative electrode must always be negative to one or the other of the positive electrodes, so that once the rectifier is started it will continue to run, using the impulse only in one direction. By this means a direct current may be taken off the negative electrode, which will be slightly pulsating,

Digitized by Google

though not so much so as the pulsating current produced by the commutator of a direct current generator.

There are other ways of operating the rectifier, so that it may be used with a single-phase alternating current. An auxiliary current may be used to keep the path through the negative electrode open, or the reluctance at one electrode may be made far stronger than the reluctance of the other. The reluctance at the negative electrode varies inversely according to the density of the vapor, which in turn is controlled by the heat generated in the rectifier. In experiments which were made with the mercury arc rectifier by the Westinghouse Company, in Pittsburgh, it was determined that when 500 volts alternating current are passed through the rectifier, direct current of between 484 and 486 volts is available at the negative electrode, indicating an efficiency of nearly 97 per cent. With smaller voltages the efficiency is slightly lower.

Good Roads Conspicuous in Canal Zone.

Although the impression prevails that except within the cities of Panama and Colon, good roads in the Canal Zone are conspicuous by their absence, P. C. Avery, of Milwaukee, who recently returned from a visit to the "big ditch," states that the impression is far from actual fact.

"The United States government has built and improved more roads on the Isthmus than it has built in the United States for a considerable period," writes Avery. "There is a fine macadamized road which would extend clear across the Isthmus if it were not for a break of 18 miles in the black swamp district of the Canal Zone. There also is a fine macadamized road leading from Panama to the old city of Panama, and the streets and roads in and about that city and Colon cannot be surpassed by those in many cities in this part of the country. The roads, too, are all posted with signs cautioning motorists to respect the 12 miles an hour law, and all vehicles, including those drawn by horses, carry lights, horns and bells."

"Tail" Lights for British Infantry.

Hereafter the British army will carry a "tail" light, so to speak. At least that is the effect of an interesting divisional order which just has been issued at Aldershot, and which requires that when the soldiers are en marche at night one of the men in the rear file carry what is styled a "reflex" light attached to the back of his belt. The device is not a light at all, though it serves all the purposes of one. It is simply a reflector, which is designed to reflect the light from the powerful head lamps of overtaking cars and thus warn drivers of the obstruction in the road. It is claimed that the khaki colored uniforms blend too well the scenery at night, and the order is the direct outcome of a previous unfortunate accident, in which a heavy touring car crashed into the rear of a column.

CANADA FOR ELECTRIC VEHICLES

Conditions That Make for Their More Extensive Use in the Dominion—Why Electric Current Is So Cheap.

"I have often wondered why there are not more electric vehicles in Canada than are in use there," recently remarked an eminent civil and mechanical engineer who has spent a good part of his life in the Dominion in the service of the government and in private enterprises of an engineering nature. "I have tried to conceive of an idea why the electric — quiet, smooth-running and efficient as it is—has failed to 'catch on,' and I must confess I am at a loss for an answer.

"It seems to me there ought to be at least as many in use in the larger cities, per capita, so to speak, as there is in the larger cities of the United States, and there are several good reasons why this should be so. First and foremost, the cost of electricity for power in Canada is but a fraction of the cost in the United States. A few years ago the cost of current was considerably higher than it is at present, though it never was prohibitive. Now, however, due to the operation of the Hydro Electric Power Commission, which was apointed in June, 1907, the cost of current has been reduced in some cases to less than half the old rates.

"By way of example, for instance, let us take the City of London. Under the old regime current cost the consumer at the rate of from 4 to 8 cents per Kilo-Watt-Hour of consumption, according to the amount of power required. At present the rate varies from 1¼ cents to 3½ cents. This is for the City of London alone, and it must be understood that the rates for other cities have been reduced proportionately to the amount of current consumed; the greater the current consumption, the greater the reduction.

"It is possible that electric vehicles would not acquire great vogue in the City of Quebec because of the exceptionally steep grades and the consequent great consumption of current; but in other cities, however, and particularly those which lie on Lake Ontario, such as Toronto and Hamilton, both of which are fairly large, there are no grades worth speaking of. Both of these cities receive part of their current on contract from the Hydro Electric Power Commission. Toronto gets the greatest part of its power from this source, though Hamilton relies for the most of it upon its own resources, which include waterpower, which permits the generation of current at even lower cost that it can be purchased from the Commission for.

"Practically every city of any size throughout the Dominon has well paved streets. In the majority of cases the pavement is a great deal better than can be found in any city in the whole of the United States. Similarly the roads are uniformally good outside the cities, at least in Ontario. But this is a matter which requires consideration in a small way, for the electric pleasure vehicle scarcely is expected to be capable of extended touring service, and the electric commercial vehicle finds its most useful field in short haul, frequent stop city work.

"It cannot be said that there is no money in the Dominion for the purchase of electricts, for the popularity of the gasolene car, which steadily is increasing, sets at naught this consideration. Commercial vehicles of the gasolene type, too, gradually are coming to be used in greater numbers. It may be that the Canadians have not yet been educated up to the advantages of the electric. In fact, it seems that that is the only reason why they are not more extensively used. Perhaps some day, when they have come to the realization of the real cheapness of electric power and of the genuine worth and surely increasing value of the electric vehicle as a means of transportation, it may become more popular, for there is no reason in the world why it should not. In the mean time, it seems that there is room a-plenty for an aggressive advertising campaign which shall undertake in a broad way to educate Johnny Canuck up to the advantages which exist in his own home."

Effect of Giving Constables Free Rides.

On January 1, 1912, when the Bavarian government decreed that no more would its motor buses employed in interurban mail delivery and passenger service be permitted to carry country constables along the highways of their districts free of charge, it was expected that this order would result in a considerable saving to the mail service department. To the surprise of the postal authorities, however, the expenses were larger than before, due chiefly to a mysterious increase of minor accidents and collisions on the highways at night. Investigation brought out that as soon as the word was passed that "gendarmes"—as the rural constables are called in Germany and France—were not transported on the mail wagons free of charge, as formerly, the teamsters decided to "forget" the law requiring the lighting of their vehicles after nightfall.

The presence of constables riding on the hundreds of mail wagons frequenting the country highways had acted as a continuous reminder of the fact that the eye of the law was watching traffic in general and the teamsters in particular. As a result, they drove carefully, refrained from falling asleep on their carts and kept their lamps properly lighted. The removal of the "free ride" privilege took that restraint from them, and accidents increased so rapidly that the government last month was forced to restore the constables' privilege of gratuitous transportation. The order went into effect immediately.

GRAMM ON GUARANTEES FOR TRUCKS

Discusses Subject in Outspoken Fashion and Points Out Purchasers' Duties—Song That Aptly Applies.

"Today the buyer of a motor truck has every advantage in the way of guarantees," says B. A. Gramm, vice-president and general manager of the Gramm Motor Truck Co., of Lima, Ohio, in discussing that very vital subject. "The present extremely high costs of motor truck manufacture are brought about largely by the unreasonable demands made by owners and operators. This, of course, is not applicable to all users, for there have always been some reasonable operators, and many are beginning to realize the advantages to be derived from dealing with the truck manufacturer who is producing a first-class truck and who, by good business methods, is making a fair return on his investment and will, therefore, stay in business. They can see how a short-time guarantee by this maker is better than a guarantee of two, five, or seven years by less conservative, conscientious and businesslike makers.

"No first-class manufacturer of motor trucks will refuse to replace a defective part, if that part be sent to him for inspection, irrespective of any guarantee he may have placed on it.

"The recent convention of commercial vehicle manufacturers held in New York, after careful consideration of the situation, recommended a ninety-day guarantee. But this does not mean that no maker will replace any defective part which may show up six months after delivery, but was adapted for the protection of the manufacturer against unscrupulous users. The time will come when guarantees will be eliminated as unnecessary. Until then, the manufacturer should insist upon the user paying, at least, for his education, instead of the manufacturer himself standing the brunt of it and paying for it.

"Experience has shown that one of the great troubles has been to convince the buyer of the type of truck he should purchase. If a study of his business conclusively showed to the manufacturer that the buyer should install two-ton trucks and the buyer absolutely insisted that one-ton trucks were of ample size, the manufacturer, rather than lose the business, has sold them, with disastrous results. The blame for all failures invariably was placed upon the manufacturer. The user claimed that the trucks were too light and would not stand the work, when the truth is they were overloaded. Had he installed the heavier model, the user would have had satisfaction from the start.

"The manufacturer lays down certain rules of proper care, and specifies carrying capacities and maximum speed limits, which if exceeded will result in withdrawal of the guarantee. No attention is paid to these requirements, but if the manufacturer does not help the user out of trouble he has gotten himself into, he threatens to trade his trucks for some other make. To the serious detriment of the truck industry at the present time, too many manufacturers are abetting this sort of thing.

"Some of the highest costs of truck manufacture are brought about because the truck maker has to provide not only the finished truck, but must bear all the burden of expense in teaching the operators, often providing even the drivers. He must either become an expert on transportation, or hire one and furnish his services free of cost to his customer, who wants an insurance against any possible loss and asks for all sorts of guarantees which are absurd on their face and which he does not get in any other line of business.

"Now, why should not the purchaser, who is to be the great gainer, be willing to pay at least for his education? There is nothing that can be done by horses in merchandise delivery that cannot be done faster and more economically by motor trucks, but as the trucks should be handled and treated in a different way from horses, the motor truck manufacturer certainly should be protected if the purchaser insists on handling the truck his own way. Every truck maker who is giving long-time guarantees, is, I am convinced, showing a weakness in his product, because his policy proves that he is selling his machines on promises and not on their quality.

"Speed governors should be installed on all trucks. It is important that they should be accurate and really govern, holding the number of revolutions of the motor down to a certain given point. However, the governor will not control a truck coasting down long grades, and it can often be tampered with by experts without the knowledge of the manufacturer. To overcome this, every truck should be equipped with a speedometer that has a maximum hand or a recorder which should be sealed or locked and the key kept by the owner. This will show the highest speed attained at any time with the truck. If a fine were to be charged against the driver for exceeding a certain speed limit, and dismissal were to follow the second fine, 90 per cent. of the present truck troubles would disappear. The song that was written several years ago, entitled, "It is not the miles we travel but the pace that kills," should be applied to motor trucks and sung all over the land.

"Last of all, tire manufacturers should take an absolute stand against overloading and report every case that comes to their attention to the owner of the truck and to the manufacturer. Above all, they should insist on the use of tires of sufficient size for the load capacity, which they can back up with their guarantees, but they should be perfectly impartial to all truck manufacturers and not give one an advantage over others, which, at the present time, they are doing in many cases."

BENZ DISPUTES DAIMLER'S GLORY

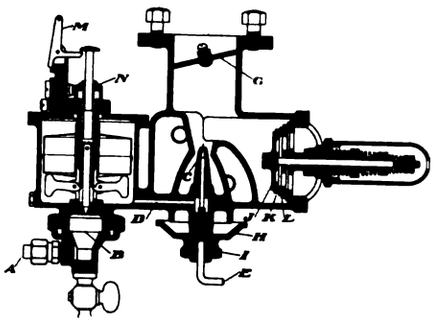
Celebration in His Honor Evokes Pointed Protest—Historical Dates That Have Been Called Into Question.

March 4th last was celebrated by the German town of Untertuerkheim as the twenty-lfth anniversary of the appearance of the gasolene automobile. The Daimler works closed for the day and festivities of a more or less joyous nature marked the occasion, which, however, served to bring public protest from the Benz company, which maintains that Untertuerkheim was not the proper place for such a celebration, and that the twenty-fifth anniversary in question occurred in 1910, almost two years before.

According to the Daimler side of the controversy which has arisen over the historical date, it was on March 4, 1887, that Gottlieb Daimler for the first time traveled over the streets of Esslingen and Cannstatt with his "benzin motor carriage," although two years before he had succeeded in propelling a tricycle by means of gasolene; but the tricycle, not being a four-wheeler, it does not, according to the German viewpoint, rank as a true forerunner of the present automobile.

The Benz protest flouts all of the Daimler claims. The Benz people state that it is a matter of record that the first automobile left the Benz factory in Mannheim in December, 1885, which original car at present reposes in the historical museum at Munich, Germany, flanked by copies of two patents issued on its construction in January, 1886, and April, 1887. The second patent covers a selective, two-speed transmission. The Benz interests also point out that at the great industrial exhibition held in Munich in 1888, a Benz automobile was displayed, thereby taking rank as the first one to be publicly exhibited.

Italy's Exports and Imports Both Increase.



Statistics of Italy's exports of automobiles, which have just been made public, show that during the year 1911 the business attained greater proportions than generally was reckoned to be the case, the shipments of pleasure and commercial cars reaching a total value of $6,291,659, as compared with $5,635,000 in 1910. The pleasure cars numbered 2,918 and were valued at $5,825,775, while $465,884 worth of commercial cars were sent abroad. The heaviest buyers of Italian cars are: Great Britain, which purchased 935 complete cars and chassis; Argentine, 346 cars and chassis; France, 242 cars and chassis; United States, 154 cars and chassis. Italy at the same time increased its imports of foreign-built cars considerably, the figures for the year 1911 being 737 cars, valued at $1,300,000, as compared with 400 cars, worth $900,000, in the preceding year.

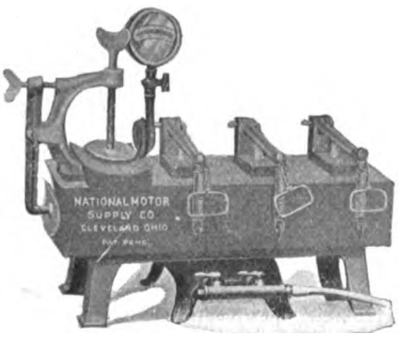
New Carburetter with Novel Air Valve.

In seeking to eliminate some of the faults of the ordinary carburetter and to provide a device which will deliver a mixture of constant proportions regardless of the quantity supplied, the Dusquesne Auto Accessories Co., New Kensington, Pa., which manufacturers the D.W.K. carburetter, has not relied on any one particular means. Instead, the method which is used to attain this very desirable end embraces a combination of features, the principle and most novel one of which is the employment of a unique auxiliary air valve, which is in reality three valves concentrically arranged.

The other features upon which reliance is placed embrace the arrangement of the component parts, which permits of a straight through passage for the gases under all ordinary running conditions, and a hot water jacket which completely encloses the whole carburetter. Referring to the accompanying sectional view, the gasolene enters via the tube A, whence it flows into the float chamber through a screen (B).



D. W. K. CARBURETTER IN SECTION

By means of a small adjustment nut, the height of the gasolene in the float chamber may be varied to suit requirements. From the float chamber the fuel passes to the needle valve (C) through the passage D, the size of the orifice at the needle valve being adjustable by means of the thread on the valve itself. Under normal running conditions, when auxiliary air is not required, air is drawn in around the spray nozzle through a passage, the size of which is governed by the air cup H, which may be adjusted and locked in place by means of a lock nut (J). As the speed of the motor increases and more air is required, it is drawn through the auxiliary air valves J, K and L, which are held to their seats by springs of different strengths. As the tension of these springs may be adjusted separately, it is possible to obtain closer regulation than is usual, which is one of the reasons for the claim of greater flexibility and greater fuel economy. To assist starting in cold weather, the float is provided with a "tickler," which permits a quantity of gasolene to collect in the small cup-shaped reservoir surrounding the needle valve. As the air enters by way of the air cup it passes over this pool of gasolene, providing a rich mixture.

Vulcanizer Designed for Garage Use.

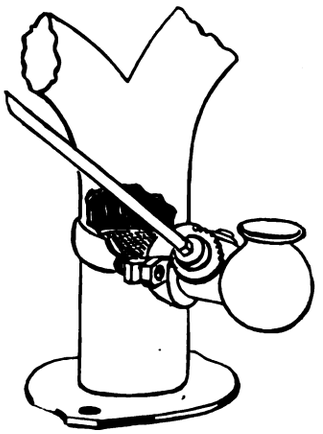
While vulcanizing often is considered a difficult and complex business, to be undertaken only by experts even when the work to be done is not large, the National Motor Supply Co., of Cleveland, Ohio, which makes a specialty among other things of vulcanizers, seeks to dispel this impression by bringing out special types of vulcanizers suitable for the use of those who, though not experienced in such work, may have occasion to repair inner tubes and castings. The latest product of this concern is a special garage vulcanizer which is capable of doing a variety of small work, such as

"NATIONAL" GARAGE VULCANIZER

vulcanizing three inner tubes simultaneously, or two sections, each 4 x 8 inches, of a casing. The tube plate measures 7 x 16 inches and the casing molds are curved both ways and will take casings of any size. Putting full sections in casings and doing re-treading is beyond the capacity of the apparatus, but it will handle all kinds of tube work and almost any other variety of casing repairs.

The National garage vulcanizer, which is of the steam type, is fitted with a steam pressure gauge, safety valve and a water plug, by means of which water can be put in the reservoir at any time. It can be heated by means of manufactured gas, natural gas or gasolene, special burners being furnished for each fuel. And, last but not least, the vulcanizer is sold at a very reasonable price.

Sapphire Tools for Hard Steels.



It is usual to consider that steel, when made as hard as possible—glass hard—is incapable of being machined in a lathe. While it is quite true that hardened steel cannot be machined with steel tools, it can be cut, and cut easily, with sapphire-edged tools, which take the metal off in curling shavings and leave a beautifully smooth surface. Such tools are ground on "laps" charged with water and diamond dust, and when properly formed and handled they are remarkably durable. On small work thousands of cuts can be taken before a regrinding is necessary. No special skill is required for the sharpening process.

Never attempt to harden a large tool in a small bath and hope for good results. Uneven hardness is sure to result.

Auxiliary Air Valve of Simple Constructon.

It is not without reason that the carburetter is one of the most abused parts of the equipment of an automobile, for the carburetter is responsible for a great deal of trouble—that is, some carburetters are, while others are comparatively blameless. With a view to the improvement of conditions where the carburetter is not all that could be desired, a device has been evolved by E. S. Michener, of New Castle, Pa., which is designed to permit the regulation of the mixture of gasolene vapor and air from the seat, without in any way altering the adjustments of the carburetter.

The device consists of a special air valve which is controlled by means of a rod and handle, the rod reaching from the dash to the valve, and the valve being attached to the intake pipe just above the carburetter. As the illustration shows, the valve has a bowl on the intake end, and gasolene can be poured into this for priming purposes, the air carrying it directly into the intake

MICHENER'S GASOLENE SAVER

manifold. A hole is drilled in the manifold and the valve clamped over the hole by means of a brass strip and nuts which form part of the outfit.

In use, the carburetter is adjusted so as to give a mixture that is sufficiently rich for easy starting and ordinary running, and the air is adjusted from the dash by means of the valve handle as the car runs, so that it is possible to obtain the best mixture under given conditions. By this method the mixture can be confined to such proportions of gasolene and air that it will burn clean, avoiding the fouling of the engine and saving gasolene, as well as getting the maximum power from the motor. When descending grades the valve is opened wide, and the throttle closed. This permits only pure air to be drawn into the engine cylinders when using the motor as a brake; it is not necessary to switch off the ignition because there is nothing to ignite, though, of course, there is nothing gained by keeping the ignition apparatus working. The Michener gasolene saver is made of solid brass, in sizes to fit any intake manifold, and is so simple as to be easily attached.

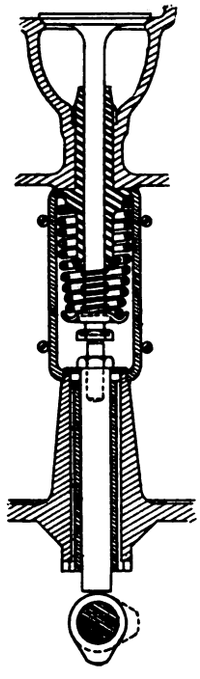
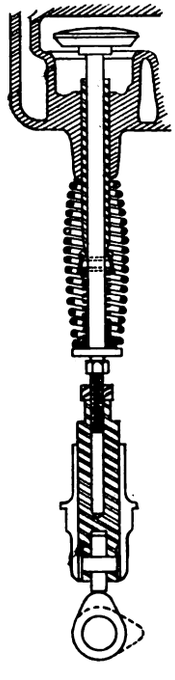
QUIETING THE ACTION OF POPPET-VALVE MECHANISMS

How Some Prominent Manufacturers Attack the Problem of Minimizing Valve Noises by Preventive Rather Than by Curative Means—The Important Part the Cam Plays and the Reason it May Conduce to Silence or to Noise According to its Profile.



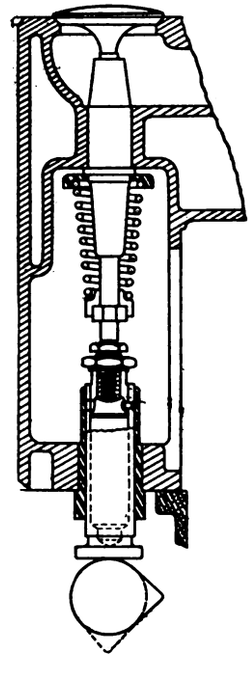
The poppet-valve motor is just as much a fixture to-day as ever it was, and no matter how careful may be the scrutiny of present conditions and tendencies, nor how elaborately facts and figures may be fashioned into its winding sheet, for use in the immediate future—its natural end is far removed, though the vision is obscured to some by the smoke the rapid progress of the "poppet-valveless" engine has made.

Despite the rapid rise of the various types of slide and sleeve and crescent and rotary and piston valve engines, and the number of such engines that are in use, the poppet-valve engine retains its accustomed niche; there has been no falling off in sales, and there are more in use now than there ever were. It is a staple that never may be wholly replaced. But there is at least one thing that the poppet-valveless engine has brought into bolder relief: It has held up to the light that existing types of poppet-valve engines are susceptible of no little improvement; it is quite natural for several perfectly obvious reasons that attention should be focused on the valve mechanism as a field fertile with latent possibilities.

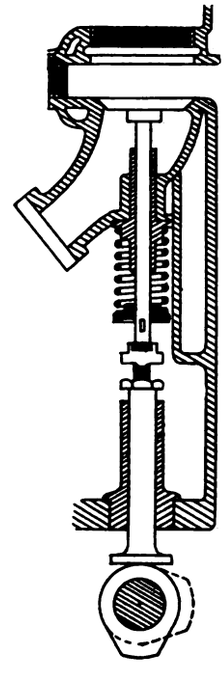


"Let well enough alone," it is to be feared, too often was the slogan of the manufacturers of a few years ago. And, sad to relate, it still is true in some few cases, though such manufacturers gradually are being reached by stray beams of light reflected from the glory achieved by the progressives. As for the latter, they have been quick to appreciate that "silence is golden," and that poppet-valve mechanism can be made a great deal more perfect than generally was supposed—as witness the latest products.

Even to the most obtuse individual it must be apparent that the search for silence is being prosecuted with greater vigor than ever before. Just how much the increasing popularity of so-called "valveless" motors has to do with the stimulus given the movement is not quite plain. It suffices, however, that motors of the poppet valve type are now far quieter than they were even so short a time as one year ago, and that there scarcely is a single manufacturer who has not within a comparatively short time adopted, or even now is preparing to adopt, some particular means of silencing valve noises.



No engine is absolutely quiet at all speeds. With the individual who is credited with having said that there are no bad whiskies, that some whiskies are better than others, it might be said that some engines are quieter than others. Vibration and noise are so inseparably linked that it is impossible to have the former without the latter, and, at present at least, it is impossible to eliminate vibration entirely. Of course, an engine must be treated as a unit, of which the valves are as much a part as are the pistons, but whereas it is possible easily to make pistons and any of the other parts of an engine so quiet as to be inaudible, the silencing of valves is, as Kipling says, quite another story; it has a moral that is plainly apparent.



OVERLAND

CADILLAC

CONTINENTAL

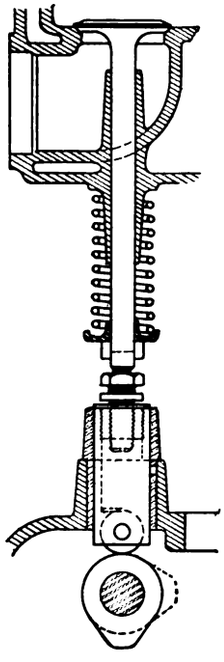
MODEL

In discussing valves and valve mechanism in general, or rather poppet valve mechanism, it is a simple matter to prove that one system is better than another if evidence touching on the quality of material and workmanship is admitted. And while such evidence must of necessity be considered, it must also be kept in the background, for though it marks the connecting link between theory and practice, and therefore is of importance, data are difficult to obtain. For a true consideration of all the systems in use, or of many of them, it must be assumed that all are of equal perfection of workmanship and material.

As applied to an automobile, the old saw "Silence is Golden" is double acting, or rather it should be so. The car that is silent, that appears to glide along without

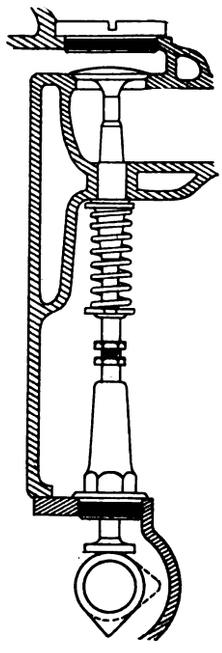
Digitized by Google

visible effort and minus audible indications that it really is running, is the car that appeals to the majority of motorists. Of course, there are those of the sporting (?) fraternity who like to be heard a mile; they consider it good advertising. But the majority prefer quiet, and consequently the quiet car should and does prove the best seller.



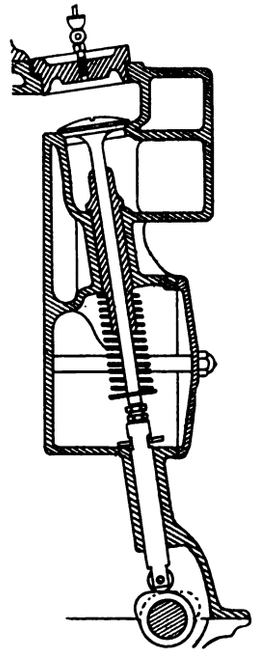
In the other light, silence should be golden, for according to engineering tenets it should indicate perfection of workmanship —the perfection that permits a tremendous electric generator, for instance, to run day and night and never emit a sound beyond a slight hum caused by the rush of air. The phrase "silence should indicate perfection of workmanship" is used advisedly. Generally it does, but quite often it does not. Which makes plain that there are two ways of obtaining silence. One of them is to obtain it by and with perfection of workmanship and design, and the other is to obtain it as a secondary consideration. Theoretically, there should be no necessity for the secondary consideration. Every part should be so perfectly designed and made that silence would follow in natural order. However, it is not always possible to follow theory as closely as is desirable, though it does not alter the fact that to prevent the possibility of noise by expert designing and workmanship is far and away better than to muffle the noise while permitting it.

Quietness of valve action does not depend alone on the actual design of the valve parts and their method of actuation, though these factors naturally play their part. For instance, a timing gear that had proved troublesome because of the noise it emitted was effectually silenced by being drilled near the periphery and the holes plugged with lead. Though the gears fitted perfectly and were well lubricated, there was a certain amount of ring to the metal which was prevented by the lead plugs. In the same way, ample water jacketing around the valve stems and guides will assist materially in reducing noise. Such little noise as there may be, and it is impossible to design poppet-valve mechanism so that it will be absolutely silent, may be accentuated by the shape of the casting and the ports. Cases have been known where, despite excellent design and workmanship, valve gear was more than ordinarily noisy simply because the cylinder casting acted somewhat like a sounding-board. Redesigning the cylinder casting so as to permit more liberal water jacketing around the valve stems and guides eliminated the noise almost entirely.

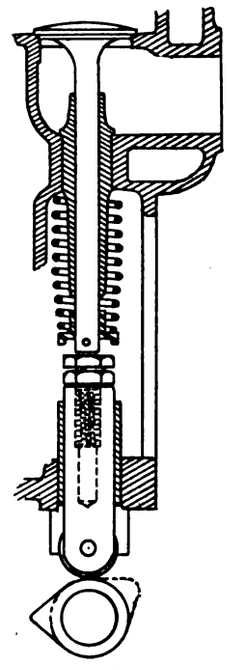


There is another important part which liberal water jacketing plays. All metals expand to a greater or less extent when heated. Because the cylinder casting is subjected to the heat of the burning mixture to a greater extent than are the valve stems, there is the possibility that the cylinder casting may expand sufficiently to permit the valve stems to fit too loosely in their guides. Obviously the result is a slight noise, which is quite likely to increase because of the wear resulting from foreign matter working in between the stems and guides. As a general rule, however, manufacturers are careful to provide ample water jacketing, and the ultimate effect on the silence of the valve mechanism is considerable.

About a year ago, when manufacturers first began to turn their attention to obtaining more silent operation of valve mechanism than previously had been obtained, the outside removable cover plate for valve springs, stems and guides sprang into popularity. Though there is little doubt but that such cover plates actually do silence valve noises to a certain extent, it is not in this respect that they are most useful. As a matter of fact, they may actually defeat their own ends by acting as sounding-boards to accentuate valve noises. That is, unless they are carefully made and fitted. Their real value lies in the fact that they serve to protect the valve mechanism from the insidious action of the grit which forms a very considerable portion of the road dirt and dust drawn in by the cooling fan and distributed indiscriminately over the engine. Thus they serve the cause of silence by reducing the wear which naturally takes place. Given a fairly silent valve mechanism, and if it is enclosed by means of a tight cover, it stands to reason that it must remain silent for a longer period than a mechanism which is not enclosed and which therefore wears more rapidly. Incidentally, the cover assists in that it permits better and more copious lubrication of the parts.



As regards the amount of play there should be between the ends of the valve stems and the valve tappets, opinions differ. Though at one time it was thought that if some means could be provided whereby the valve stems and the tappets could be maintained in constant touch noise would be practically eliminated, experience has proven that such is not the case. Innumerable methods of attaining just this end have been suggested, and a great many of them have been put into use, but at the best they serve only to prove that the source of noise must be searched for elsewhere. Owing to the fact that the valves themselves expand slightly under the action of the heat combustion, it is necessary to allow a certain amount of space between the stems and the tappets when the valves



RAMBLER

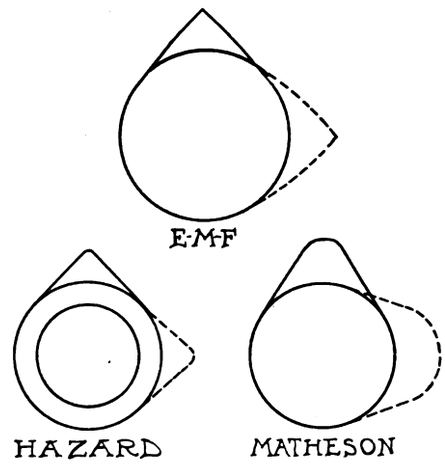
SPEEDWELL

KING

BEAVER

Digitized by Google

are closed. Theoretically, this distance should be just such that when the valves have reached maximum expansion they will seat perfectly when closed. It is difficult to gauge this distance, however, for even two valves of the same size and material may expand differently, due either to the local heat being greater in the region of one of them or to some slight difference of composition which cannot be detected. Consequently, most manufacturers adopt an arbitrary limit to which all tappets are set. The clearance between the valve stems and tappets in Hazard motors, for instance, is .005 inch for exhaust vales and from .002 to .003 inch for intake valves; Velie valves are adjusted for a clearance of .005 inch, and by way of pointing out the diversity of opinion that prevails, the clearance in Continental motors is as low as .002 inch.



But as great as has been the achievement of quietness by reducing the amount of clearance between the valve stems and the tappets, and by careful water jacketing and adding well-designed, snug-fitting valve spring covers, by far the greatest advance which has been made is in the profile of the valve cams. A very few years ago a cam was a cam, and nothing more. Cams were designed primarily to open the valves and to hold them open for a certain length of time, according to the individual ideas of the designer. Provided the end in view was attained—i. e., the valve opened and closed at the proper time, and the horsepower chart showed what in the estimation of the engineer was a sufficient percentage of the indicated horse-power available—there was an end of it. In other words, it was a case of "Let well enough alone."

But now things are different. Though it has been known for a long time that cam profiles play an exceptionally important part in the production of power and the silence of operation of the engine, it is only comparatively recently that manufacturers have viewed their cams in the right light and turned to them, almost as a drowning man turns to a straw. The result is that in a remarkably short space of time cam profiles have changed almost beyond recognition from their original shapes. And the most interesting part of the whole thing, the part which actually proves the wisdom of the manufacturers in substituting new cams for old cams, is that the efficiency of the engine has increased in no small measure, and lack of noise, that chimera which every manufacturer earnestly is chasing, now is more complete than it ever was before.

In the first place, a cam must open a valve quickly and maintain the passage for the gases open during a certain portion of the stroke of the piston; also it must close quickly. In action, the push rod, sliding over the cam, is pushed upward and transmits the movement to the valve, which opens. As the cam rotates still further, the push rod follows the contour and lowers the valve into place again. Which is all very well and good as long as the rate of cam rotation is low. But, when the speed of the engine is increased and consequently the speed of the cam, there is a tendency for the push rod to "jump"—to fail to follow closely the contour of the cam.

It is the duty of the valve spring to maintain the valve tappet and the cam in constant contact during the whole of every revolution. If the cam is of such shape that there is considerable tendency for the tappet to "jump," it then becomes necessary to use a fairly heavy spring pressure. The higher the spring pressure, of course, the greater will be the wear on the cam and the camshaft bearings, and, unless the cams are carefully designed with this contingency in view, the greater will be the noise caused by the seating of the valves.

However, that the spring pressure is not governed by the shape of the cams entirely

CAM PROFILES THAT DIFFER

may be judged by comparing the following table with the shapes of the cams as shown in the accompanying drawings, which are made to scale and represent the various valve mechanisms in use as they are:

Motor.	Valve Diameter, Inches.	Valve Lift, Inches.	Spring Pressure, Pounds.	Seat Angle, Degrees.
Rutenber	2	3/8	65	45
Speedwell	2 1/8	5/16	46	45
Great Western	1 7/8	3/8	In 45 Ex 50	45
Cadillac	1 3/4	11/32	45	45
King	1 13/16	5/16	45	45
Winton	2 1/16	In 5/16 Ex 11/32	60	45
Chalmers	In 2 1/4 Ex 2	1/4 9/16	35 45	Flat 45
Pullman	2 1/8	3/8	40	45
Rambler	1 11/16	5/16	60	45
Overland	2 1/8	In 3/8 Ex 7/16	40	45
Matheson	2	3/8	85	45
E-M-F	2 3/32	1/4	30-38	45
Hazard	1 5/8	9/32	In 24 Ex 30	45
National	3	1/2	In 80 Ex 90	45
Velie	2	3/8	45	45
Peerless	1 3/4 2 2 1/4	5/16	40 45 55	35
Falls	2 1/4	5/16	65	45
Packard (6)	2 1/8	3/8	50-53	45

By way of still further illustration, the cam profiles as used in E-M-F, Hazard and Matheson engines are shown herewith, drawn to scale. Though it might appear that owing to the comparative sharpness of the E-M-F cams the spring pressure would require to be greater owing to an apparently greater tendency to cause the push rods to "jump," the actual pressure used is as low as from 30 to 38 pounds. Hazard cams, which are slightly flatter, require even less spring pressure according to the investigations of the designers, the best effects being obtained with 24 pounds pressure on the exhaust cams and 30 pounds on the inlet cams. Matheson cams, on the other hand, and the exhaust cam in particular, are very much flatter, and yet the valve spring pressure used is 85 pounds. None of these engines is noisy, and the Matheson engine in particular is noted for its quietness of action.

Obviously, the weight of the valve itself has considerable to do with the spring pressure which must be used and with the silence which can be obtained. For instance, if the valve is heavy and the cam is rotating rapidly, the inertia of the valve will be considerable. In order to overcome it, the valve spring must be increased. Consequently, not a few manufacturers have concentrated their efforts on decreasing the weight of their valves. The differences in weight which obtain may be judged from the pictures. Some of the valves, it may be seen, are much lighter than others, and, all other things being equal, they should be the quietest. There is a limit, of course, to the degree to which a valve may be lightened. There must be a certain amount of metal in order to stand the strain and to retain its shape under temperature changes.

Valve seat angles, as a rule, are 45 degrees, though there is a notable difference in the case of Peerless engines, in which the angle is but 35 degrees. At any rate, 45 degrees appears to have become standard. With a very much smaller angle there is danger that the valves may stick, and with larger angles noise is increased slightly.

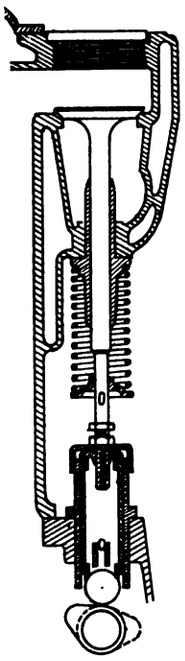
In the case of the engine used in Overland cars, the designers have adopted a novel method of ensuring the lubrication of the push rod and valve stems. The push rod works in a die cast bushing inserted in the crankcase. This bushing has two grooves in it which serve to return oil, trapped in a recess, to the crankcase. The oil is prevented from splashing out by a steel washer. The upper end of the push rod contains a set screw, which has a fiber insert upon which the end of the valve stem bears. On the lower end of the valve stem guide a recess is made in which is placed a felt washer, held in place by a steel cap and a light spring, which is supported by the valve spring cap. When the mechanism is assembled the washer is soaked in grease, which lubricates the valve stem and also prevents the leakage of gases. The whole assembly is enclosed by means of a split housing, the removal of which exposes all the parts for adjustment or replacement. In the Cadillac engine a similar arrangement for lubricating the valve stems is used, though the push rods are lubricated by splash from the engine crankcase.

Continental practice embraces the use of

Digitized by Google

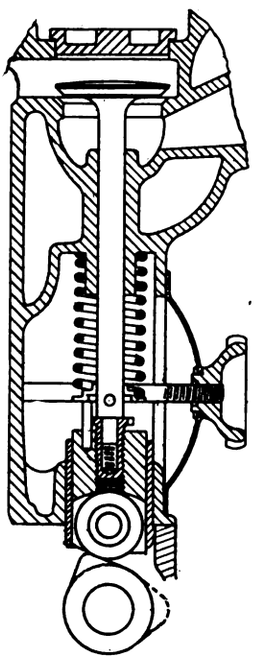
slightly crowned push rods, which construction, according to the manufacturers, "seems to do more than anything else toward reducing noise." "This probably is due," explains W. A. Frederick, of the Continental Motor Mfg. Co., "to the push rods being slightly out of square with the camshaft, and the push rod when ground flat would bear on the corners, while if slightly crowned the bearing point would be in the center of the push rod. The cam should strike the push rod in the center, thereby allowing the push rod to rotate and distributing the wear evenly." Such crowning now is used extensively by other manufacturers as well.

Similarly, the extension of the "foot" of the push rod also is universal practice, as it tends to reduce the side thrust given by the cam to the push rod. The illustration of the Model engine shows this feature well, and a little study of the drawing will make plain the theory involved. The valves of the Model engine are rendered more silent by the insertion of the fiber plugs in the ends of the tappets. Rambler practice also embraces the use of fiber-tipped valve tappets, which construction eliminates the metallic click which offends the ears of some. Speedwell practice is slightly different in that the push rod guides are entirely outside the crankcase. Otherwise the construction is orthodox, and silence is obtained by careful workmanship and adjustment.



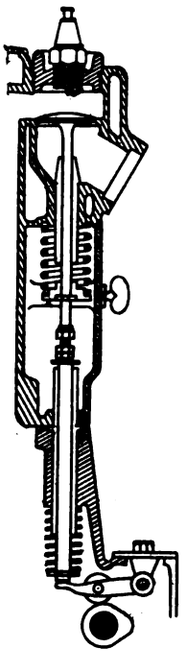
Instead of providing a plain surface at the end of the push rod to bear on the cams, quite a number of manufacturers incline to the use of roller contacts. As to whether this construction is better than the other is a matter of opinion. Suffice it to say that the number of exponents of each method of construction is very nearly equal, and some manufacturers even make both styles. Beaver motors, for instance, are made either way, the roller style of push rod contact being illustrated. In King engines, the roller contact also is used, and the whole mechanism is slightly out of the ordinary in that the valves are inclined at an angle toward the combustion space. The inclination, however, is not by way of increasing the quietness of the mechanism, but rather to increase the efficiency of the engine by bringing the valves closer to the combustion chamber, and thus reducing the distance the gases must travel and quickening the rate of flame propagation.

Packard construction also embraces the use of a roller contact between the push rods and the cams, and the quietness of the mechanism is insured through lubrication and protection from the ingress of foreign substances. The push rods work in bushings in the crankcase, the joint at the sliding contact between the push rod and the bushing being protected by a tight-fitting cap. Packard engineers were among the first fully to realize that lightness of valves and valve parts plays a very important part in the ultimate silence of the engine, and to this end the parts have been made as light as is consistent with the work which they must perform. As an instance of the thorough manner in which the problem of lightening the parts has been attacked, the push rods, instead of being solid, which is usual, are made of cold-drawn seamless steel tubing.



Fairly large valves with a comparatively small lift are the features which makes for silence in Winton engines. These, with careful design and workmanship, including a tight-fitting protecting cover, insure the minimum of noise and the least possible fear. The lubrication of the push rods is effected by splash from the crankcase.

To avoid side thrust by causing the cams to move the push rods straight up has been the object of the manufacturers of Rutenber engines, who have evolved an exclusive and distinctive method of valve actuation, which is noted for its quietness of action and its wearing qualities. As may be seen in the accompanying illustration, the cams do not bear directly on the push rods, but actuate levers which in turn move the push rods. By reason of the construction, the cams which are used may be considerably smaller than is usual because of the leverage which is obtained. The actual amount of lift that is imparted to the levers is multiplied two-fold by the outer end of the levers, where they come in contact with the push rods. Incidentally, this method of construction permits very close adjustment, which, with a tight-fitting valve spring cover, decreases audible sounds to the minimum.



After all, the problem resolves itself into a question of perfection of design first, perfection of workmanship second, and perfection of material third. Some engines embrace all three considerations, and consequently are quiet—even as quiet as any of the various poppet-valveless engines; others embrace but two of the considerations—either two—and are not as quiet; and others embrace but one consideration and are noisy. When all engines are built around the three considerations, which scarcely is possible, all will be uniformly quiet, and though it is doubtful that such an event ever will come to pass, it is perfectly apparent that present-day engines are more quiet than were their immediate predecessors. Similarly, it is quite probable that the engines of the future will be even more quiet than the engines of the present.

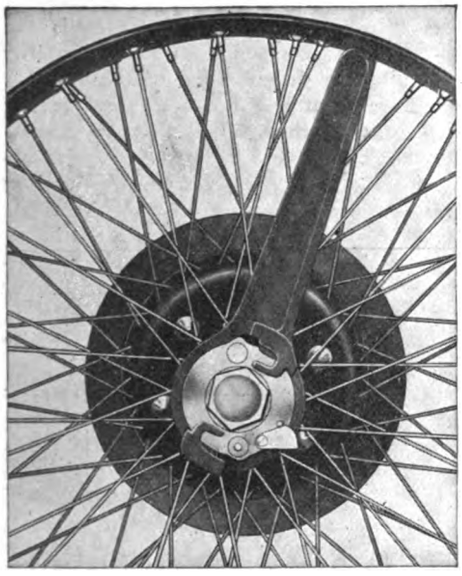
WIRE WHEELS AS REAL FACTORS

Backed by Previous Experience, McCue Takes Up Their Manufacture in Earnest —Features of His Productions.

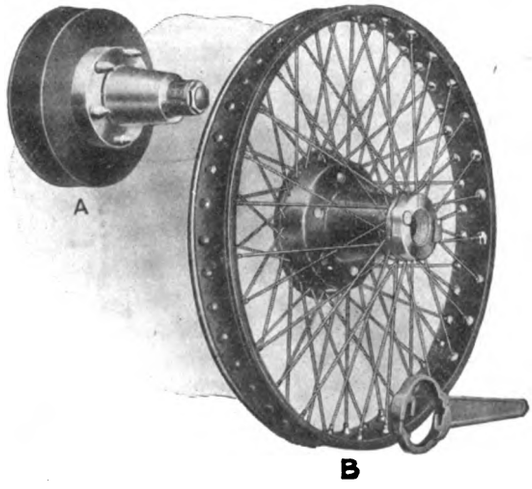
It undeniably is true that there is a growing sentiment in favor of wire wheels, and unlike other sentiments which have sprung from almost purely esthetic motives, it is backed by real reasons of quite another nature, reasons that appear to be well supported by proofs of tire economy that are nothing short of remarkable, and which are wholly apart from those which induced the use of enlarged bicycle wheels when the automobile was very young and very tender. Though it has been said that the British are notoriously slow to take up with anything until its worth has been demonstrated, they have taken quite readily to the wire wheel, and despite opinions to the effect that it is virtually "Hobson's choise," the tests which recently were conducted by the great English Daimler company, by which it was claimed that as much as 70 per cent. greater tire wear was obtained from tires fitted to wire wheels, scarcely can fail to allay the suspicion.

Of course these tests were conducted under almost ideal conditions. The roads abroad are well known to be better than the roads in America and the cars were driven by expert chauffeurs. Inasmuch as the cars were "let out on hire," to use a British phrase, it is inconceivable that they were driven at high rates of speed. But even in view of such considerations, if the tire economy was even half as great as is claimed, and there is little reason for supposing that it was not, there is just cause to sit up and take notice. At any rate, the experience of motorists who have used wire wheels in America under other than ideal conditions, in long cross country tours, where the roads encountered were good, bad and indifferent, appear to substantiate the claims for considerably greater tire economy. At least, those motorists who have used wire wheels have nothing against them, and though few can exhibit accurate data, the consensus of opinion is that tire wear is less, resiliency is greater and the danger of accident due to fractures is considerably reduced.



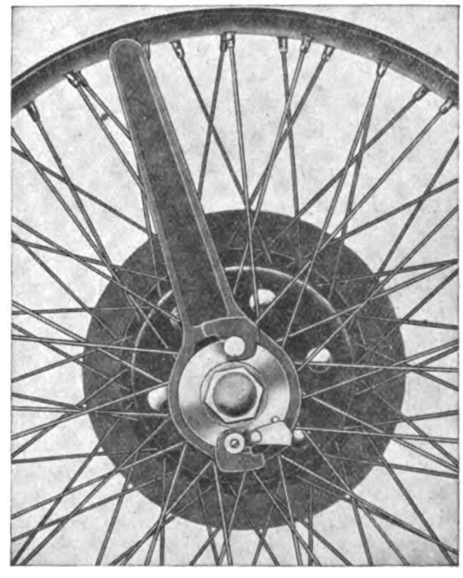
In view of these facts, it is perhaps surprising that American manufacturers have not previously seriously considered the wire wheel. It is known now that several prominent manufacturers are experimenting with them with the view to their possible utilization in the near future, and it is freely predicted that there will be a rush for wire wheels in 1913. The wire wheel itself is neither new nor novel, of course, and is largely a heritage from the old bicycle days. As to why the wire wheel should be better than the wooden artillery wheel for automobile use, there probably is no better simple exposition of the theory, the way and the wherefore, than that which was given by H. L. Heathcote, B. Sc., a noted British engineer, in a paper which he read before the Royal Society of Arts in England.

"Wheel building is the counterpart of tire inflating," he said, "and the art produces its best when sufficient tension to produce torque rigidity is combined with conditions that develop in the wheel a maximum cushioning effect. Such a wheel by co-operating in the duties of the tire, lengthens its life and lessens its liability to wear, cut and puncture. Both the wheels of antiquity and the artillery wheels for motor cars owe much of their lateral strength to the high moment of inertia of their heavy woodne felloes, the disadvantage of which is their inflexibility and their inability to absorb shock."



The wire wheel overcomes practically all these difficulties. First and foremost, it is a tension wheel, the hub, and consequently the weight supported by the hub, being suspended from the rim by means of the wire spokes, which generally are about 72 in number. Consequently, the load is more evenly distributed over the spokes than it is in the case of a wooden wheel. Furthermore, it is more resilient by reason of the properties of the materials of which it is made. And last, but not least, because of the comparatively thin section of metal on which the tire is mounted, greater facility for heat radiation is afforded. This, in itself, it is stated by eminent tire authorities, is a feature which should conduce to lessened tire depreciation, for it is well known that heat has a deleterious effect on rubber.

So far, but one American manufacturer seriously has taken up the production of wire wheels for automobiles. That company is the McCue Co., of Buffalo, N. Y. Despite the fact that the McCue company only recently undertook the manufacture of such wheels, the undertaking is far from being in the nature of an experiment. The McCue company, as is fairly well known, had made wire wheels for a long term of years, and during the pneumatic tired carriage period, from 1895 to 1907, the experience with thousands of sets of wire wheels has been that tire wear has been increased as much as 100 per cent.



The McCue wheel, as may be seen by the accompanying illustrations, follows closely the general lines of accepted practice abroad and consists of the hub (A) which is rigidly attached to the axle of the car, and the demountable wheel (B). Completing the equipment is a special wrench which forms a very important part of the assembly, inasmuch as dependence is placed upon it to insure that the wheel is positively locked in place when once applied. To remove a wheel, it is merely necessary to apply the wrench, which, by reason of its construction, and the con-

APPLYING THE WRENCH

HUB (A) AND DETACHABLE WHEEL (B)

WRENCH IN POSITION

Digitized by Google

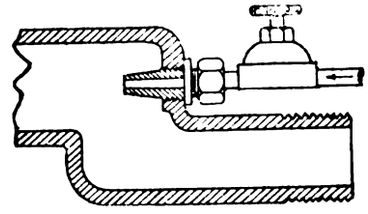
struction of the locking mechanism, automatically releases the locking dogs, when a few turns screw the wheel off the hub. When a new wheel is applied it is impossible to remove the wrench until the wheel is securely locked. In other words, the locking of the wheel automatically releases the wrench, which then may be removed.

In summing up the advantages of the wire wheel, President C. T. McCue, of the McCue Co., points particularly to the saving in weight which it permits. "Five detachable wire wheels," he says, "will weigh very much less than four wooden wheels with demountable rims and the usual fifth demountable rim carried. The cost to begin with may be a trifle more, but eventually that will even up. For the present, or until the wire wheel is used exclusively, the manufacturer of cars will require axles so designed that either wood or wire wheels can be used, and if the English practice is followed, the wire wheels will all be enameled black, the same as fenders are now made, so that the car manufacturer can assemble his car with a finished set of wheels for any car he may make."

Proper Way of Caring for Chamois.

While most people think that one piece of chamois leather is as good as another for the purpose of cleaning automobile bodies, the careful garage man soon discovers that one will give good service, while the other will scratch the polish after a single day's use. Sometimes it's the fault of the cleaner in not properly caring for the leather, but more often it is the fault of the buyer in not selecting a good leather. Many will accept the first skin that is pased to them, when as a matter of fact a very careful selection should be made in order that the softest may be secured. A new chamois cannot be used on the body of a car because of the fuzz that it leaves behind it. The first ten or twelve times that it is used it is full of an oily substance, and for the purpose of being "broken in" it is advisable to use it on the running gear first, because this part of the car does not call for such high polish as the body. Once the leather is broken in, it is important that it be kept very clean. It should be soaked in soapy water without much lye and then put through a wringer. The best way to thoroughly clean a chamois is to put it flat on the washrack and scrub it with a soft soapy brush, all the while allowing a stream of water to run over it. If it is too greasy, the oil can be worked out readily in distillate of gasolene, and the leather then be forced through a wringer.

Mirror That Serves Useful Purpose.



While the trick is of course a very old one, it often is not remembered that a small mirror is exceedingly useful to reflect a ray of light on a dark spot on a motor; for instance, the breaker box of a magneto. This is particularly useful where the motor is not very accessible and examinations have to be made at long range.

SIMPLIFIES WATER CIRCULATION

Attractive Device That Employs Exhaust Gas for the Purpose—Drawbacks That Actual Use May Develop.

During all of that period which served for the introduction of new and radical ideas into the design of nearly all of the vital parts of the motor car, and during which ignition, lubrication, transmission and carburation systems were brought to their present state of comparative perfection, it is significant that but two methods of causing the circulation of the cooling water have been employed—movements by means of convection currents and movements by means of a mechanical pump.

It is true that changes have been made in the design of the apparatus incidental to the correct operation of both systems; that

OWERS'S "INJECTOR" PUMP

the radiator has assumed various forms; that the shape and the scope of the jacket around the cylinder have been altered somewhat, and that where a pump is used to circulate the cooling medium, improvement in design and in the method of drive have not been lacking. But the fact remains that no really new method of propelling the liquid through the jacket, radiator and connecting pipes has been developed.

Recently, however, a device of that sort has been brought out by Owers & Son, of Chiswick, England, and naturally no little interest attaches to it, for not only is it charmingly simple, but apparently it combines the good points of both the pump and the thermo-siphon cooling systems. The device, which is shown by the accompanying illustration, consists of nothing more than a section of pipe bent twice at right angles and having a small nozzle projecting into it. The part into which the nozzle projects is slightly larger in diameter than the rest of the section. The operation is simple in the extreme. The pipe connecting with the nozzle conducts a stream of the gas from the exhaust manifold, and the impact of this gas at relatively high velocity against the water in the pipe causes the movement of the liquid. It is claimed that the circulation caused is much more rapid than can be attained with the thermo-siphon system, even with the aid of specially large connecting pipes, while all of the mechanical difficulties of the pump system and all of the dangers consequent on the breaking of the pump driving shaft are avoided. The quantity of water circulating through the system can be varied at the will of the operator simply by opening or closing the cock which limits the supply of burned gases, and the design being simple, no reason exists for not incorporating the apparatus directly in the cylinder casting.

As is the case with everything possessing virtues, it is not at all unlikely that the "injector" or "aspirator" also will have its drawbacks, which will tend to limit the scope of application. Naturally, the introduction of the warm gases will tend to increase the temperature of the cooling water, and this is hardly a desirable feature; but it is not probable that this trouble will be so great as to need attention, since the tube through which the gases are injected is said to be but ⅛ inch in diameter. The composition of the exhaust gases is the stumbling block which in all probability will stint the development of the practice. The gases contain, besides a great quantity of nitrogen, carbon dioxide, carbon monoxide, free carbon and unconsumed hydrocarbons. If the water used in the cooling system were perfectly pure at all times, the negative effects consequent upon the introduction of the exhaust gases would be confined to the slight amount of harm caused by the solvent action of the hydrocarbon and the carbonic acid, which is formed by the carbon dioxide in the water. If, however, the water contains certain more or less common salts in solution, and this is generally the case, the presence of the carbon dioxide causes precipitation of insoluble salts, and this is especially true when the water is warm. As a result, it is not unlikely that "furring" of the radiator would be a much more common occurrence with the "injector" than with the present systems, and that the cooling water would have to be renewed quite frequently. The simplicity of the contrivance is so impressive, however, that it wisely cannot be dismissed with a breath.

To Prevent "Furring" in Radiators.

"Furring" in the radiator is in most cases caused by the formation of calcium varbonate, which is precipitated from the water when heated. If sal ammoniac, which is the commercial name for ammonium chloride, be added to the water which contains calcium carbonate the result would be the formation of calcium chloride and ammonium carbonate, both of which are soluble. The insoluble carbonate then could be removed.

Why Water Level Falls in Radiator.

It not infrequently happens that when an empty radiator is filled up and the car run a short distance the water level will be found to have fallen considerably, though no overheating has occurred and no leak exists. The reason is that the water requires some little time to percolate through the various restricted passages in the cooling system, and a little "shaking down" results in a falling of the level.

POINTING THE EASY ROUTE TO GETRICHQUICKLAND

Astonishing and Enticing Means Employed by the "Greatest Automobile College in the World" to Catch the Would-Be Chauffeur's Coin—"Masters of Gas Engines" Evolved in Twelve Weeks, and Before Graduation, and After, There's Money, Money Everywhere if Not a Cent to Spend.

Ordinarily, the prospectus of an educational institution is about the most cut-and-dried bit of literature the printer is called upon to turn out, and anyone who sends for one knows just about what to expect. The curriculum is innocent of the feeblest germs of humor, and after extracting a few essential facts and noting that, as usual, the place ought to be a health resort, so salubrious are the climatic and sanitary conditions, the catalog is forgotten. Correspondence with an institution of learning cannot be expected to increase the pulse rate to any appreciable extent; and as for the matter of fees, they are fixed and unalterable. The whole business is prosaic to the point of absolute dullness—and the reality usually is exactly what it is pictured, in every way.

But as a breaker of images, a destroyer of traditions and a shatterer of ideals, that ultra-modern institution, the "automobile university" without the least doubt is entitled to the palm. Its literature is filled with surprises, its advertisements, placed freely where they will be seen by those for whom they are intended, are amazing in the exuberance of their promise, and the unconscious humor of their correspondence caps the climax. So far have some of these "colleges" departed from scholastic custom and tradition that the whole thing actually is a huge joke from beginning to end. From the modest admission, printed on the front cover of a representative catalog, that the establishment is "the greatest school of expert automobile engineering in the United States" to the shrinking statement on the last page that "there is no other school like it," the catalog ought to be worth its weight in gold to the dyspeptic, for there is a laugh on every page.

While there is a good deal of sameness about these "automobile engineering universities" in the matter of advertising—and in the schools themselves, for that matter—some carry the principle of "anything to get the money" to greater lengths than others. Advertising in technical and semi-technical periodicals usually is the first step, and the men who are of the sort to be impressed by the "gorgeous, glittering, oh-listen-to-the-band" (as the circus press agent would say) prospects that are held out by these literary gems are just the men who might be expected, and are expected, to "send for our catalog." And the picture of one of these simple-minded fellows perusing the pages and the reams of printed and typewritten and mimeographed stuff sent to him through the mails is rather pathetic and more than a little calculated to arouse indignation, for the whole business is so cunningly planned as to appeal not only to the cupidity of the indolent ne'er-do-well, who, in his ignorance, thinks he sees the gates of prosperity standing ajar, but also to the ill-informed but really ambitious youth who has an honest desire to make something better of himself and who is willing to devote his scanty savings and his infrequent spare hours to the task.

Perhaps the most daring and enterprising, and therefore the most interesting (from a certain point of view) of these loud-talking "colleges" is "The Automobile College of Washington," of Washington, D. C. A perusal of the voluminous letters and the school prospectus, which requires at least three good looks to distinguish it from a motor car catalog, reveals the fact that the "Automobile College of Washington" purports to be a good deal more than its name implies; without doubt it actually is something more than a mere educational institution, as will appear later. The "college" boasts that "we consolidated with 'The Carter Motor Corporation,' in whose factory the 'Washington 40' is built, and we now have the further advantage to speak of that we are the only school in the world which trains its students right in the factory." This statement is apparently given weight by the printing in the pamphlet of a number of views of cheerless factory interiors, with such captions as "Our students assist in all kinds of construction work" and a repetition of the ubiquitous phrase "The only school in the world training its students," etc. There is a reproduction in the back of the catalog of a letter from the Carter Motor Car Corporation expressing satisfaction in the "graduates of your college we have employed" and stating that graduates of the "college" will be given the preference when men are being taken on. Notwithstanding all the palaver about "consolidation" and "factory training," the Carter Motor Car Corporation went into bankruptcy about two months ago—despite the free labor supplied by the "college students."

Among the very first of the college's amazing propositions offered is "our automobile agency plan." A conspicuous page in the catalog is devoted to the setting forth of the "plan," and is headed, "Our course prepares you to earn $4,800 a year, or more." Briefly, the "plan" is that "all those who become students of this college will be made sales agents for the Washington cars, shown in this catalog, the price of which is $2,250 for either model, fully equipped. We will allow our students a commission of $400 on each car they sell." And rubber stamped on one corner of the page is the information that owing to the reduction in the price of the car from $2,250 to $1,750, the commission shrinks to $175 for each car. But the catalog goes on to say that any student who purchases a demonstration car will be given "our course free of charge." And the siren sings on, "It should be a very easy matter to sell a car a month, and that would mean a yearly income of $4,800 to the agent. Suppose you only sold six cars a year, that would bring in a profit of $2,400 a year." The rubber stamp does not explain how these figures agree with the reduction in the price of the car or the considerably more than corresponding drop in the amount of the commission. Perhaps it would not sound quite so enticing. It is earnestly urged that all those who purchase demonstrating cars proceed to Washington and "complete our course right in the factory," so that the "agent" will be enabled to make more sales. "However," continues the catalog, "we will appoint you as our agent whether you purchase a car or not, and will supply you with catalogs, printed matter, etc., if you become a student of this institution." It is impossible to escape the conviction that if the authors of this naive bit of printed matter had half as much faith in the "plan" as they struggle to instil into their readers they would be earning "$4,800 a year or more" by following their own directions.

This, however, is not all, by any means, for it would appear that the "Automobile College of Washington" is a good deal more interested in giving young men opportunities to get rich—and incidentally to peddle the wares of the A. C. of W.—than in educating them. The further the catalog and the letters are perused the deeper the path leads into marvelous "business opportunities" and the further it gets from its supposed subject—a technical education. "The very day you enroll," the flow of language ripples on, "you may" (note the gracious permission) "begin to send in the names of young men whom you think might be interested in our course." It is estimated that half of such young men will enroll, and as the school pays $3 a head for every student brought in according to this plan, it is suggested that "you should

Digitized by Google

pay for your course several times over in this manner." At this point the reader who values his sanity should hastily turn over to the next page and look at the pictures, for if he stops to think he will presently be lost in a maze of calculations that will make a mere bagatelle of the mathematical gyrations of the man who figured the descendants of a single hen for a few years into the future. If every student paid his way through "college" several times over—or even twice—the entire District of Columbia soon would be required for the campus, and the bursar would be kept busy paying for new students at a rate that would increase beyond the capacity of the most capacious adding machines. And if students just paid their way through once, there would be nothing doing but instructing pupils free of charge and putting up new "college buildings" to take care of the increase. Doubtless this possibility led the "faculty" to adopt the "agency" plan, which provides for a little unencumbered income for the "college."

However, the ramifications of this very versatile institution have not all been explored. Read on. "If you wish to travel," begins the next explosion of beneficence, "we have one of the largest automobile supply houses in the country, and the very day you enroll for our course we will make you our agent for this department and we will pay you $1 for each new customer you secure for us," to say nothing of a commission of 5 per cent. on purchases made by such customers. This, it is cheerfully maintained, will provide a steady income "without any effort on your part." Again it seems hard to realize that men should be willing to sacrifice their lives in teaching when there is so much money to be picked up "without any effort." But the large-hearted faculty of the A. C. of W. will do even more than this.

Even after a student "graduates" and has been solemnly invested with a diploma (by the way, "when you have earned this diploma you are a master of the modern gas engine") he is not forgotten by the faculty, for the catalog says so—and, besides, a school that turns out men who are made capable of earning "$4,800 a year or more" naturally likes to keep in touch with some of the $4,800 if possible. Therefore, "if you desire to go in business for yourself, we suggest that you let us select a good town for you when you graduate, and from the repair business, the agency for the Washington car and the sale of automobile supplies from our supply department, and as special representative of our school, you should have a big income all the year round." This particular part of the matter is too important to be lightly passed over. Near the end of the catalog, just before the pages of sickeningly sweet "testimonials," a couple of pages are devoted to an array of figures and statements that are calculated to make the reader wonder how it is possible to keep any able-bodied man out of the automobile business. "$21. a day" begins this part of the story, in letters so big that they nearly fall off the page. "We start you in business for yourself." ($20 a day would have been a smooth-sounding phrase, but the odd dollar sounds so much more accurate!) It seems, according to the prospectus of this "educational institution," that there are openings for garages and repair shops in a thousand small towns where "amazing profits can be made." A "detailed statement" is given, showing just how "an average profit" of $21 a day can be earned. All that is necessary is to open the garage—there are no expenses connected with this ceremony, apparently; the garage will be all ready for business as soon as the "graduate" steps in—do eight hours work a day on repairs, at a dollar an hour; sell 100 gallons of gasolene, paying 10 cents a gallon and getting 18 cents; dispose of 15 gallons of 30-cent lubricating oil at 80 cents a gallon, and store 15 cars at $15 a month. This totals $31 a day. Then you have to pay an assistant repair man $4 a day, a washer $2 a day, the landlord $75 a month, and for everything else —covered by the term "incidentals"—$1.50 a day. That leaves a net profit of $21 a day, clearly. That is, there ought to be no trouble in making $6,573 a year if the "graduate" has religious scruples and won't work on Sundays, or $7,665 a year if he is a heathen and keeps the doors open seven days a week. But that is not the limit, apparently, for the catalog says "Any experienced man will tell you these figures are conservative. Twenty-one Dollars a Day!" So far as this particular page is concerned, the college would apear to be entirely disinterested; it is a clear case of "helping our graduates to get started in business." But the next page is given up to the other side of the shield, so to speak. "We Supply Tools and Select Towns Where You Start." The tools are supposed to cost from $50 to $100, this to include "all necessary tools for opening the repair shop." This has a burglarious sound, and doubtless $100 worth of tools would suffice to "open the repair shop," but it is quite unnecessary to say how far they would go toward keeping the shop open, to say nothing of earning six or seven thousand dollars a year. But the school again shows wonderful confidence in its graduates. "You can pay part of the cost of the tools out of your daily profits, or at your convenience." Note the word "part." It is not discoverable from a perusal of the catalog or the accompanying literature what proportion this "part" bears to the whole price of the tool outfit, but it is a pretty safe assumption that in case the student graduate fails to clear six thousands a year the "college" will not lose anything on the transaction. The page winds up with an impassioned exhortation to consider the magnificent prospects spread out. And, as if this were not sufficient, it goes a step further and actually advises the borrowing of money from friends "who might help you with a small loan." Here the appeal direct ends, as well it might. It could go no further without suggesting—too much.

Evidently, however, the "college" finds that there are a good many young men who do not respond readily to the first treatment of catalog and three-page imitation typewritten letter, for it is prepared to keep up a systematic bombardment of correspondence that might be taken to indicate that the "college" needs somebody's money very badly, or else that it has the inside track on the price of postage stamps. Letter after letter, and sheaf after sheaf of fac-similes of testimonials, telegrams from automobile manufacturers (marked "paid") beseeching the "college" to "send from fifteen to twenty-five" men, or "send any number of men up to fifty," and so on, keep the postman busy. Finally, after all this has failed to touch the "prospect's" heart (slang for purse), the "college" sends out its masterpiece—its final thunderbolt. This surpassing effort begins with a solemn asservation, "This is the most important letter that you have ever received." The next sentence is touching: "In several letters recently we have tried to give you a truthful idea of the grand opportunity that the automobile business presents to you, but we seem to have failed, inasmuch as you have not enrolled." A series of conjectures as to why the opportunity has been neglected for such an unconscionable length of time follows the opening, and finally the thing that makes this epistle "the most important letter that you have ever received" is brought to light—the secret is revealed. "Here is our confidential message." It needs no detailed explanation or lengthy quotation to convey the information that the "confidential message" consists of an offer to chop off part of the price of the course and let the student pay what is left almost any way he pleases—he even can wait till he has received his education and pay the last installment after he has secured a job! But—"Keep this offer confidential. Special confidential blank is enclosed. It is good for ten days only." Then a few gentle reminders to the effect that such a remarkable offer will not go begging; some other fellow will get his eagle eye on it and snap it up. "For ten days it remains up to you, then, if you don't act you have lost out and the other fellow will be the gainer." Accompanying the letter is a "special" enrollment blank, on the face of which the regular prices and terms are ruthlessly scrambled and scratched with a pen. The use of a well-worn rubber stamp to put on the word "Special" somehow conveys the impression that so many of these special and confidential documents are issued that the labor of writing it with a pen would be excessive. Unfortunately, there isn't space between the lines to alter the prices and terms with rubber stamps—and it certainly wouldn't look well to have these confiding missives printed. Still another document accompanies this fearfully important letter, and lest it should be unnoticed, it is decorated with a huge and

Digitized by Google

very red seal— a real seal, stuck on very tight, and occupying a vast area of perfectly good white paper. Under the heading "Notice" come the information that this special offer is made "to Mr. —— —— only," and also that it is good only for ten days from the date, which is carefully inserted in red typewriting in two separate and distinct places. But—it simply is amazing how many "buts" there are in this collection of literature—the last paragraph sets forth, "Reasonable extension of this time limit will be granted"—note the large-hearted generosity—"when request is accompanied by satisfactory reasons."

Having made matters so extremely clear in so many different ways, and having made so many perfectly good and extremely elastic offers in dissolving figures, it might with reason be assumed that the "college" would have reached its limit and that lack of response would cause the very cold "prospect's" name to be withdrawn from the follow-up card index and the astonishing offer passed on to the "other fellow," who might be expected to be very tired after waiting so long for his chance. But not a bit of it! A little later along comes another letter, which begins by expressing curiosity as to why there has been no response to all the offers and appeals and confidential opportunities that must have cost so much postage money to send out, and goes on to recapitulate. The letter abounds in such expressions as "improving your circumstances by a clean and well-paid profession"; "the reasons why you should learn automobile engineering as a profession"; "the only school in the world that trains its students right in the factory"; "do you realize what it means as a life profession?" and so on. Medicine, law, dentistry and engineering are compared, much to their disadvantage, with "our course," which, it would appear, can be covered in ten or twelve weeks, after which the graduate is supposed to be able to launch forth and make half the lawyers, doctors, dentists and engineers in the country hide their diminished heads for shame.

All this sort of thing is very much of a joke to anyone of average intelligence who has read as much advertising matter as have most Americans, and it is so preposterous to those who are familiar with the "automobile business" that it inspires a feeling akin to disgust. Starting out under a high-sounding name as a school, the "Automobile College of Washington" glides easily and naturally into the position of a dealer in anything and everything pertaining to the automobile, and beseeches everyone with whom it can get in touch to become its agent. Commissions are paid on new students brought in; on new customers for "one of the largest supply houses in the country"; on supplies sold; on motor cars sold; students are set up in business—buying their tools and supplies from the "college"—and, in fact, one who takes the "course" is permitted, with overwhelming graciousness, to do practically anything—that will bring money in for the "college." Apparently these student-agents must be profitable to their "alma mater," for it is certain that no stone is left unturned to induce them to "enroll"—even to the extent of urging them to borrow the money.

While on first thought it might be considered unnecessary to call attention to the ridiculous and misleading stuff printed by self-styled automobile schools, the mere fact that such enterprises exist in large numbers and apparently are flourishing is sufficient indication that a great many men must be so loosely attached to their money that they can be persuaded to hand it over in exchange for a "diploma"—or else can detach the price "from a friend." As a matter of actual fact, the ranks of the unemployed are crowded with chauffeurs, good, bad and indifferent—and numbers of them are the proud (!) possessors of diplomas which seem to have lost their job-getting powers since coming into the possession of the present owners. Anyone who wants to try it can get his pick of any number of chauffeurs for an average price per week that is considerably lower than the lowest mentioned in the literature of the "colleges," and a man of only ordinary ability who knows nothing and depends for a livelihood—to say nothing of such things as "easy work and big money"—upon a job as chauffeur is reasonably sure to be kept hustling for work. Of course, a first-class man, be he chauffeur, repair man or what not, usually can do fairly well; but the point is that it is no more possible to give a man all the training he needs for such a position in 10 or 12 weeks than it is to make a doctor of a high-school graduate in a year. A man may well spend a lifetime in study and practical work, and yet be far from claiming to be a "master of the modern gas engine"; nevertheless it is claimed by these so-called colleges that ten or twelve weeks is sufficient time. And as for the possibility of earning "$4,800 or more" a year in any one of a thousand small towns by opening a garage and repair shop—even with the solicitous assistance of the "college"—it is necessary only to find out how many proprietors even of large garages are doing as well, to say nothing of the ridiculous idea of clearing from $6,500 to $7,500 a year in a garage renting for $75 a month and employing two men besides the proprietor. It may be that such things are possible; there are combinations of circumstances that might work miracles, so to speak; but it is quite certain that a twelve-weeks student, with no other knowledge or experience than that extracted from an "automobile college," would not come within a hundred miles of "twenty-one dollars a day."

Horse Driver Gets a Prison Sentence.

For driving a loaded wagon, drawn by two horses, along the public highway between two small villages in central Germany, and causing an accident to an automobile in which the owner of the car was fatally injured, a farmer named Sebastian Roth was sentenced to two months imprisonment. The court lectured him severely on his carelessness; and, despite the fact that the German highway laws do not specifically demand the lighting of wagons in sparsely settled districts, sentenced him under the statute which makes it a misdemeanor to be the contributory cause to an accident.

Emir "Orders" Roads for His Motor Cars.

There are things in which an absolute monarchy, or autocracy, is infinitely superior to a republican government—as, for instance, in the matter of road building. The best roads of olden times were built by the Romans during the reigns of their various Caesars—than whom no present potentate is more autocratic—and the worst roads are in the United States—a modern republic! It takes so long to pass a bill for road improvement, and, after it has been passed, so much of the money voted goes into the pockets of individuals instead of into the road surface, that republican roads are slower in building and more costly than any other kind. All of which serves to emphasize the power of the Emir of Afghanistan, who, by a stroke of his pen, has "ordered" the construction of a complete macadam road system for his kingdom, so as to permit of his use of the various motor cars which he bought a few months ago. The road system will cover the entire country and will aggregate over 10,000 miles, two of the more important highways being 300 and 400 miles in length, respectively. At the present time there is barely ten miles of road in Afghanistan suitable for automobile travel. The project will involve the construction of roads blasted along the sides of precipitous mountains, miles of which will be literally "in the clouds"—the plateau over which the roads lead being the highest in the world, reaching to 20,000 feet, while some of its peaks have an altitude of 25,000 and 29,000 feet.

Must "Furnish Required Identification."

Despite the fact that the New York Court of Appeals has ruled that the provision of the Callan law compelling a driver of a motor car to testify against himself in case of a collision by forcing him to remain on the scene of the accident and to give his name and address to questioning policemen or eye-witnesses, is unconstitutional, other States continue to hold opposite views. The latest decision upholding the constitutionality of such a provision in the automobile laws of a State is reported from Missouri. The opinion was rendered by Judge Withrow last month, and overruled the motion of counsel for one Forbes Kneedler to quash the indictment charging him with running away from the scene of an automobile accident. In his opinion, the judge declared that the law requires a person in an automobile not to "furnish evidence against himself," but to "furnish required identification."

COMMON TOOLS THAT ARE ABUSED

Part of Cars' Equipment That is Given Small Consideration—Glaring Errors of Inexperienced Users.

In any branch of applied mechanics it is not at all unusual to find that consequences are of a magnitude all out of proportion to their causes; in other words, that little things can cause a great deal of trouble, and, conversely, that equally little things can save a great deal of trouble. While this truism has been iterated and reiterated and used and re-used until it is almost threadbare, so far as the motor car and its various details are concerned, it has not been so overworked in its relation to the tools that are used by every man who takes care of an automobile, whether it be his own or the property of some other man. At any rate, an inspection of the tool kits of the majority of motor cars will indicate that the users of the tools either lack knowledge of many very simple little things or they fail to appreciate their genuine importance and do not make use of the ounce of prevention that proverbially is worth sixteen times as much in the way of cure.

Some people who take care of automobiles cannot be mechanics, and some don't want to, and so they hardly can be expected to pick up the thousand and one little scraps of practical information that are part of the journeyman's stock in trade. But almost anyone is likely to use a cold-chisel occasionally when working on a car, and it is a surprising thing to see what a difference it makes whether the chisel is ground as it should be or as it should not be. This tool should not be ground perfectly straight across the edge; it should be very slightly rounded—only very slightly—and it will be found to cut better and quicker and to hold its edge better than a chisel with a straight edge. Moreover, in chipping off any quantity of metal, for instance from a casting, the round-edged chisel will get a better bite, start more easily in hard places, and will not dig in at the corners, which not infrequently break off in the case of a straight-ground chisel. Of course, if too much curve is given to the edge there will be a tendency to dig in too deeply and break away the edge at the middle. A chisel which breaks at the edge simply because it is too hard, usually will be found about right if it is ground back to the end of the break, provided the piece broken out is not a large one.

The common idea seems to be that because a cold-chisel is a tool for cutting metal, and that it is driven to its cut with a hammer, it doesn't particularly matter whether it is sharp or not; so the average cold-chisel is indeed a sorry-looking, blunted-edged, battered bit of steel. Any doubt on this point will be instantly dispelled by a practical test of two cold-chisels, one dull and the other properly sharpened. Of course, where a cold-chisel is habitually used for starting nuts that are hard to move, it doesn't do to have it sharp; but the fact of the matter is that a cold-chisel should not be used in this way. If a nut has to be forcibly persuaded to turn, the tool should be ground flat across the end and one of the right-angled edges applied to the nut. This form will result in the least possible cutting of the nut and will transmit to the nut the maximum power from the hammer blow.

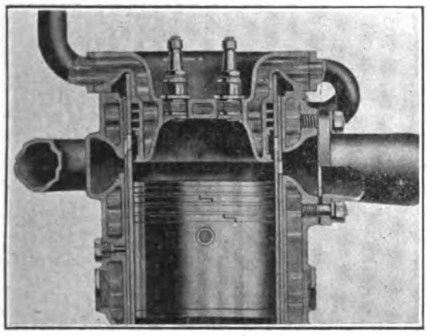
There are a great many cases where the cold-chisel is used to start a nut just because the nut has had its corners "chewed off," in the vernacular, by the careless use of the wrench—which goes to show how very easily one evil can lead to another, while the second leads to the scrap-heap and also to the hardware store for a new nut. Things are not quite as bad in this respect as they used to be, but, really, the usual condition of the wrenches in the tool box is such that a chauffeur, upon seeing a good set, will involuntarily ejaculate, "Gee, look at the swell wrenches!" The trouble is that the average run of human nature is apt to use the first wrench that will stand a pull without turning on the nut, whether it is a proper fit or not—especially if time presses. If the wrench fits snugly, well and good; it will stand pulling to the limit of its strength and will do no harm to the nut or to its own jaws. A solid wrench—that is, one that is not adjustable as to the width between its jaws—will last for years if properly handled. But if it is too large for the nut it will jam down the corners more or less, according to how much too large it happens to be, and at the same time spring its jaws apart, if sufficient pressure is applied. And the trouble does not end here, for if a nut is much battered up it will play havoc even with a wrench that normally should fit it, jamming between the jaws and springing them and causing wear. About this time the mistreated nut is ready to be "agitated" with a hammer and chisel—a proceeding which, by the way, often results in the hitting of something that really ought not to be hit with the hammer, barked knuckles and various other things of which most chauffeurs, at least, don't need to be reminded.

As for the poor old monkey wrench, it is enough to say that the average tool of this type that has been "in business" for any length of time has sprung and worn jaws, a bent back, an uncertainty that is painful in the action of the adjusting screw, and a head that is all battered up—because the wrench was handy and the hammer wasn't. Wrenches sometimes can be used as hammers when nothing more severe than a gentle tapping is required; but they are not by any means good for this purpose. Moreover, the steel is necessarily too soft to stand the banging; if it was hard enough for hammer work it would be too brittle to stand the breaking strains to which a wrench normally is subjected. It is a mechanical crime to tug at a nut with an adjustable wrench that is not screwed up to fit the nut as closely as possible; to put any strain on it when placed on the nut with its jaws parallel with the axis of the nut; and to pull on it in the wrong direction—that is, so that the back of the tool will be in the lead. This is the cause of "bent backs," for a monkey wrench has much less stiffness when used in this way than when properly used—with the jaw and screw side leading.

Files and hack-saws find prominent places among the crippled and battle-scarred legions of ill-used implements. There is a prevalent notion that these tools are designed to scrape or scratch when at work, so it comes that the unfortunate tools are simply scraped back and forth without rhyme or reason; usually nearly as much pressure is applied on the back stroke as on the forward stroke. The fact of the matter is that these are really cutting tools, and that they cut only in one direction—on the forward stroke. Pressure applied on the return stroke is worse than wasted, for it has a tendency to spoil the cutting edge of the teeth, especially in the case of the saw. And another unappreciated point is that the best cutting speeds are different in differently spaced teeth and in different metals, and a little feeling out will indicate when the metal is cutting best. A big 16-inch mill file cuts best if used with a rather slow stroke but with heavy pressure, while a fine file should be run faster and with less force. In the case of the hack-saw, the speed is of less consequence. For all-round work a medium-sized tooth is best, but for cutting pipe or thin metal better work can be done with fine teeth, which do not stick when going through.

It would be an easy matter to go through the whole list of ordinary mechanics' tools and indicate similar abuses and misuses, all leading to ultimate trouble and expense and loss of time, temper, knuckle-bark and so on. But enough has been said concerning some of the very commonest tools in use to convey the idea that a very little carelessness can make a great deal of trouble, and a little trouble taken can save the infliction of a great deal of it.

To Start Car if Crank is Broken.



The usual method of starting the motor when the crank is broken is to get the machine rolling and drop in the clutch with the gear in high. If no means of acquiring the required momentum are at hand, and the motor cannot be started by priming and turning on the spark, chock one of the rear wheels so as to prevent the car rolling, jack up the other rear wheel and put the gears in high. By turning the wheel which is free from the ground the motor can be started, but extreme care should be exercised to prevent the jack from falling. This method should never be tried unless a competent person is in the driver's seat.

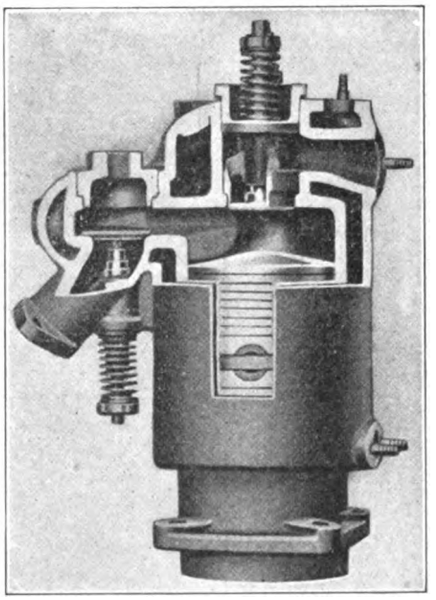
COMBUSTION CHAMBERS; THEIR SHAPES AND EFFECTS

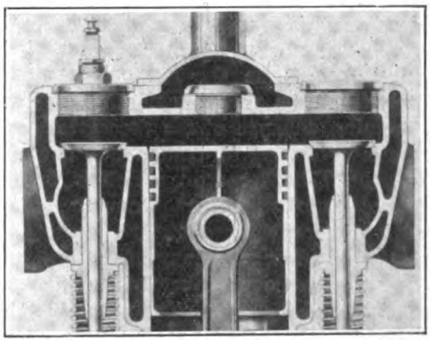
One Feature of Gas Engine Design in Which Theory and Practice Cannot Always Be Reconciled — Practical Considerations That May Offset Theoretical Advantages — Wide Variations in Use That Are Highly Efficient Despite Their Divergencies.



It may be that the time will come when the exigencies of practical design in the internal combustion motor field will not seriously interfere with the adoption of forms that are best theoretically. But that time has not yet arrived; it is well known that in many details there is a great deal of difference between gasolene engines as they should be and as they really are. The reason is that no one part can be built without reference to other parts, for the efficiency and practicability of the engine as a whole depends upon the harmonious working together of all parts. There are many parts which, if constructed strictly according to theory, would so hamper the functions of other parts that the loss entailed in this way would more than offset

COLUMBIA-KNIGHT DESIGN

the gain resulting from the theoretical correctness of that one part. As a matter of fact, the whole gasolene motor is a compromise between what is possible theoretically and what is attainable practically, and the form of the combustion chamber—the space between the top of the piston and the head of the cylinder, into which the combustible charge is forced just prior to ignition—is an interesting case in point.



Theoretically, the best shape for the combustion chamber is a sphere. The internal combustion engine is a heat motor, and, as its name implies, the heat which it converts to mechanical energy is generated within itself by the combustion of gases. Obviously every heat unit that is wasted means just so much lost power, and so the form of combustion chamber that involves the least heat waste ought to materially increase the efficiency of the motor. The wall surface of a spherical combustion chamber is of less area, in proportion to its cubic contents, than that of any other form—less by 33 1-3 per cent. than the area of the walls of a cylindrical combustion chamber of equal capacity; and, the radiating surface being less, more heat will be retained and less lost through radiation and consequently the lowering of the pressure of the ignited gases will be lessened. But here practical considerations interfere. In the first place, the piston itself, which must be concave to form the lower part of the spherical chamber, has very little opportunity of getting rid of heat; there is a slight cooling effect from the air on the underside, and the rest of the heat must be transferred through the cylinder walls to the water jacket. A concave piston

STERLING COMBUSTION SPACE

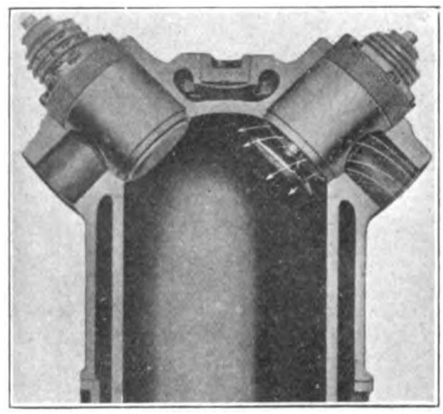
head, having a greater surface area than a flat head, of course, will absorb more heat, and often concave heads have been found to take up more heat than they could get rid of—in other words, they overheated. Nevertheless, this difficulty is not insuperable, for there are many engines built and successfully operated with spherical combustion chambers. To cite a conspicuous example, Knight motors are built with concave piston heads and with cylinder heads which, while not hemispherical, are of truncated cone form, thus exposing to the heat an area that is almost as small as that of a hemisphere.

In the Knight engine, however, such considerations as the location of intake and exhaust passages and valve chambers do not here enter into calculations of the designer, the sliding sleeves closing the ports and forming a combustion chamber that is extremely symmetrical and conducive to heat economy—in fact, the form of the Knight engine combustion chamber is responsible for an appreciable share of the high efficiency of the motor. In poppet valve motors a combustion chamber that is approximately a hemisphere can be obtained only by placing the valves in the cylinder head. This is done in the Jackson motor, for example, and the result is a combustion chamber that is of excellent form, from a theoretical point of view, and that is practical in operation. The combustion chamber of the Franklin motor, on the other hand, is purely cylindrical, though both valves are located in the head.

PACKARD T-HEAD CYLINDER

The use of valves in the head involves overhead valve gear, however, and this is a form of construction that is not in favor with most manufacturers, notwithstanding the excellent results that are obtained from motors of this type. There are motors, such as the Model and the Sterling, though the latter no longer is manufactured, in which there is one valve, the exhaust, in the head of the cylinder, operated by overhead gear, while the intake valve is located in a pocket which forms an extension of the combustion chamber. While the formation of a pocket for the intake valve destroys the symmetry of the combustion chamber, the advantage of a very large exhaust valve can be retained and the valve is very accessible. At the same time, the valve pocket or chamber is not very large, in proportion to the cubical contents of the combustion chamber as a whole.

While the motors employing the valve-in-the-head construction, with either one or both valves in the head, are numerous, the more general types are those known as

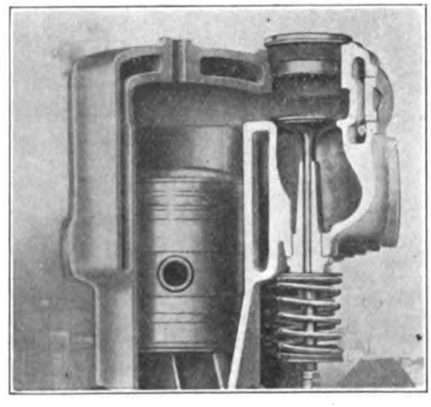


Digitized by Google

the L-head and T-head motors. In the L-head motor both valves are located in a single large pocket on one side of the cylinder, and in the T-head type there are two valve pockets, one on each side, the letter-like shapes given to the cylinder castings by the projecting pockets naturally suggesting the descriptive designations popularly applied to motors. The Stevens-Duryea motor is an excellent specimen of the L-head type. Both types have in common the advantage that there is no overhead valve gear, all the valve operating mechanism being positioned far down and in a protected position, and such motors can be built of minimum over-all height. In the L-head motor all the valves are actuated by a single camshaft and the intake and exhaust piping is confined to one side of the engine, leaving the other side clear.

Obviously, these two combustion chamber forms are anything but theoretically correct, especially that of the T-head motor, in which the two side pockets serve to increase very largely the radiating surface and also contain gas that must require more time to burn than if the entire charge was contained in a single symmetrical space so that the flame would not have to travel the distance from the spark plug, which very commonly is placed over the valve pocket, to the remotest corner of the chamber, which in the case of a T-head motor, would be at a considerable distance. In seeming defiance of the theoretical considerations bearing on combustion chamber form, the T-head motor, which is further removed than all others from the shape that it theoretically ought to possess, is remarkably efficient. Many of the best cars built embody this manner of engine construction, and it is particularly notable that most of the phenomenal racing motors have had their valves in pockets on opposite sides of the cylinders.

The apparent lack of agreement between theory and practice involved in this detail of combustion chamber form is strikingly illustrated by the fact that two of the most efficient motor types that have been evolved employ combustion chamber forms that are almost opposites. The Knight engine, on the one hand, has a combustion chamber that is almost perfect, theoretically, and the work of the motor requires no comment. The T-head motor, on the other hand, necessarily is made with little regard for compactness of the charge, yet there is no question whatever as to the practicability of the design and the excellence of well-built motors of the T-head design.



It does not follow, because motors having theoretically imperfect combustion chambers give results in actual operation that are on a par with motors that are more nearly theoretically perfect in this respect, that there is anything wrong with the theory. The trouble is that when it is necessary to sacrifice other features of construction in order to secure a correctly designed explosion space, the losses balance the gains—or so nearly balance them that the choice of combustion chamber form is of less importance than the perfection of other parts directly affecting or affected by it. The correctness of the theory is exemplified by the Knight motor, in which the theoretical form is possible without sacrificing anything in the way of practical con-

JACKSON OVERHEAD VALVES

siderations—rather, theory and practice work together in complete harmony, neither being sacrificed for the other.

As a matter of fact, and as in all other branches of engineering, progress in motor construction is made largely by reconciling practicabilities with theories—by working out mechanical details so that they permit the use of wholly scientific design. And while it is unlikely that it ever will be possi-

STEVENS-DURYEA CONSTRUCTION

ble to bring about a complete agreement between theory and practice, it is a certainty that the motor of the future will be nearer to theoretical correctness in the same proportion that it is superior to the motor of the present time.

New Method of Making Metal Leafs.

By reason of the inordinate costliness of the operations necessary in the manufacture of metal leafs, such for instance as gold leaf and silver leaf, the finished product is expensive and far beyond the intrinsic worth of the materials, and its use therefore is limited. Recently, however, a British patent, No. 27,020, has been allowed on a new process of manufacture which should materially reduce the cost of metal leafs and so bring them into more general use, which, though restricted at present, might be extended to the plating of the reflector portions of lamps and for other purposes in the manufacture of automobile accessories. The product obtained by the new process is styled artificial metal leaf and can be made of any desired thickness; furthermore, it is sufficiently flexible and ductile for embossing in high relief. So far, only bronze leaf has been produced, though the simplicity of the process points to the possibility of its employment for other metals. The metal in powder form is mixed with collodion or some other similar medium and sprayed to the desired thickness on glass, metal, paper or any other substance, which may be either rough or smooth. As soon as the layer is dry, the glass, or whatever the leaf has been deposited upon, is placed in water to detach the foil.

Speedometers as Aids to Gear Shifting.

Though speedometers generally are used to ascertain the speed at which the car is being driven, or to determine that the legal rate of speed is not being exceeded, there is another use to which they advantageously may be put; i. e., they may be used to determine the exact moment when it is proper to change gears. Of course, the time when gears should be shifted will vary slightly, according to the conditions under which the car is being driven, but once it is determined that the engine behaves best at, say, ten miles an hour when second speed is engaged, it may be taken as a criterion that when the speedometer hand points to ten miles an hour and any other gear is in mesh, a change to second speed should be made. If, for instance, the car is being driven through traffic and a momentary slow down to ten miles an hour is necessary, a glance at the speedometer will suffice to allay speculation as to whether gears should be shifted or not. Similarly, when a hill is negotiated, immediately the speedometer shows a predetermined speed, or rather just before it does, assuming the car has gradually slowed down, gears should be shifted. Thus the engine and the car will be saved the unnecessary racking caused when the engine commences to labor.

Polish That Injures Nickeled Trimmings.

In polishing the silvered reflectors of lamps, or the nickeled trimmings that are becoming so popular on motor cars, it is well to bear in mind that every rub means the wearing off of a little of the plating, and that in time it will wear through. A great deal depends upon the kind of polishing material used; a harsh, gritty polish will wear down the plating quite fast, while a good polish will ensure maximum life of the finish.

THE THREE KINDS OF OVERLOADING

Tire Expert Defines Them and Details the Trouble and Expense They Cause—Remedies Which He Suggests.

While the mutual interest of tire makers and manufacturers of motor truks in the matter of tire life is a subject that has been discussed frequently and at length, it was dealt with in a somewhat unusual manner in the paper "Detrimental effects of overloading and overspeeding on solid rubber tires," which was read by S. V. Norton of the B. F. Goodrich Co., before the recent convention of commercial motor vehicle manufacturers held in New York under the auspices of the commercial vehicle committee of the N. A. A. M.

Norton consistently and naturally took the side of the tire maker, and pressed the claim that there is a good deal of overloading of tires for which the truck manufacturers are directly or indirectly responsible, such as the use of tires too small for their work and the improper distribution of weight, so that some tires are overloaded while others carry less than their share of weight. A third kind of overloading that came in for condemnation was the too common practice of faulty distribution of lading, which usually is done to facilitate the handling of goods. The belief was expressed that there should be a more complete understanding between the two classes of manufacturers, which would give tire makers a chance to make valuable suggestions as to the use and care of tires after leaving their hands. Norton's paper in full was as follows:

"Just what is meant by the overloading of rubber tires? In the process of manufacture crude gum is mixed with pigments and the whole mass is kneaded together until the compound becomes homogeneous. After various intermediate steps, the rubber is placed in a mold and vulcanized. During vulcanization the tire assumes a more or less permanent form, to which it will normally return if it is not stretched or compressed beyond certain definite limits. If the stretching or compression exceeds these limits, however, the strain will invariably cause a rupture or disintegration of the rubber.

"To illustrate: Take a strong, properly vulcanized rubber band. Stretch it moderately, release it and it will return to its normal shape. The process may be repeated indefinitely, depending upon the quality of the rubber, and the band will resume its shape. Stretch it beyond its limit of elongation, however, and what happens, The rubber breaks and all the king's horses and all the king's men can't restore it to its previous condition. The damage has been done and the rupture is permanent. Similarly a piece of rubber properly vulcanized maly be compressed within certain limits, released and it will resume its normal shape. The compression may be repeated an indefinite number of times, depending upon the quality of the compound. So long as its limit of compression has not been reached the rubber will continue to spring back into shape and nothing but abrasion or some other physical or chemical action will destroy its 'elasticity.' Compress it beyond its limit of cohesion, however,—or, in other words, beyond its power of resistance —and the rubber breaks down or ruptures just as inevitably as in the case of stretching beyond its limit of elongation. The rupture is absolute and permanent. No method yet devised will restore to the unit its former 'elastic' qualities.

"I have brought a number of pieces which have been broken down in our laboratory by repeated compression and release to show you the nature of the change in the rubber. The difference between this rupture and that brought about by stretching, however, is that in the latter the tear usually results in a clean separation, while in the former the rupture may not be noticeable because the broken parts are held in place by others not yet noticeably affected. Nevertheless, the damage is done, and disintegration has commenced—not because the average load exceeded the limit of resistance, but because some one load exceeded it and started the rupture. If I can impress upon you, gentlemen, the great danger of ruining solid tires from once overloading them and the consequent necessity of explaining this matter convincingly to your agents and demonstrating operators as well as the users and prospective users of trucks, I shall feel gratified.

"Tire manufacturers, after years of observation and experiment, have adopted a schedule of carrying capacities which with but slight variations is now considered standard. It seems hardly necessary to repeat the figures at this time for they are given in every tire manufacturer's catalog. Let me say, however, that the factor of safety in the schedule is nil. So many other factors enter into the matter, such as excessive strains due to bumps, depressions in the roadway, negotiating grades, overspeeding and the severe use of brakes, that no provision has been made for overload.

"There are three kinds of overloading to which I should like to call your attention. In doing so I may be in danger of repeating the mistake recently made by Senator LaFollette in his Philadelphia address, namely, accepting the hospitality of an organization and then telling its members how wicked they are. But if I seem to indicate that there are weaknesses in the policy of some truck manufacturers I do not attribute them to selfish motives, but rather to an incomplete knowledge of the economics of the subject.

"The first kind of overloading is due to undersized original tire equipment. I fully realize that the competition in your business makes it necessary for you to economize wherever possible in the equipment of your trucks. You build the best machines that money and skill can devise and you offer them for sale fully guaranteed—except for tires. Without knowing the danger you are running, you may perhaps equip them with the smallest tires that will come within our schedule of carrying capacities. Then, if for any of the reasons I shall mention later, the tires fail to deliver the service expected, the responsibility is at once automatically shifted to our shoulders and we are expected to live up to our reputations for liberally taking care of our product. Suppose your sales agents order just the chassis and then have special bodies built—bodies too heavy in themselves, or so large as to permit the carrying of loads far in excess of those the tires are able to sustain without breaking down. What happens? Your customers soon have trouble with their tires and they complain that the cost of maintenance is more than they had been led to believe.

"The second kind of overloading is due to disproportioned equipment. Sometimes we find that trucks whose tire equipment, regarded as a whole, is ample for the service required, will be lacking in carrying capacity at one end while at the other end there may be an excess capacity over the actual demands. I have in mind a case in which we were called upon to make an adjustment. The proportion of weight carried by each axle showed that the front tires were considerably overloaded while those on the rear had an excess capacity of nearly a ton. The owner of the truck protested his innocence, saying that he had never been told he was misusing his tires. The difficulty once explained, however, and the proper sized front tires applied, there was no further trouble.

"The third kind, which is at once the most prevalent, the most illusive and the hardest to cope with, is due to the improper loading of the commodity upon the truck. Sometimes this may be the result of faulty distribution of the load over the front and rear axles, which may cause the failure of the tires wholly without the knowledge of the owner. This is well illustrated in the following quotation from a paper read by one of our representatives at a conference of truck tire salesmen and adjusters at our factory a few days ago:

"'In the case of a wholesale grocer it was discovered that it was a custom to put all light packages on the front of the truck and save the heavy ones for the rear, with barrels of pork, molasses, sugar and kerosene on the tailboard. In another case the loads of leather board, which were comparatively small and carried but short distances, were all placed at the rear of the truck.

"'In a coal concern the loose load was distributed in the truck body and then the rear was piled up with bags of coal. In each of these cases the total load was within the combined capacity of the tire equipment but not properly distributed.

"'In our judgment improper loading

Digitized by Google

must be shared jointly by the maker and his representatives, and by the user. How far the user is to blame varies, and it is a question whether in most cases he is to blame at all.'

"By far the most difficult phase for the tire maker to overcome, however, is the deliberate placing of too heavy loads on the truck as a whole for the tires to carry. The way is paved for the abuse even before your prospect has bought a truck. I refer to the temptation to which some of your salesmen yield to carry heavier and bigger loads than they should when they give demonstrations before a prospective purchaser. When it becomes known that a man is thinking of buying trucks he is besieged by agents asking the privilege of giving demonstrations. A fierce competition then ensues to win the order, by showing how much merchandise may be moved within a given period, and how fast it can be carried. The result is that some of the loads carried in these competitions vary from 50 per cent. to over 100 per cent. over the rated capacity of the tires. I believe that most of these abuses occur without the knowledge and consent of the factories making the trucks, and in certain instances in deliberate disregard of the orders from headquarters.

"One reason for the continuance of this practice is the direct result of the well known policy on the part of many tire makers, of renewing without charge, or perhaps for a nominal charge, such tires as are broken down or worn out on demonstrating trucks for the sake of the advertising value derived from having the tires used. It has always seemed to us that this policy acts as a boomerang to the tire maker, because it is a direct incentive to the ambitious demonstrating salesman to disregard all responsibility for the proper care of the tires in service; no matter how badly they are misused, he doesn't have to foot the bill. And he fails to realize that he is setting a bad example to the man who may be the future owner or driver of one of his trucks. But, in many cases, regardless of the original training and explanations given to a driver, there is always the temptation to fill the truck to the limit of its physical capacity to move the goods. The merchandise must be moved, and 'a load is a load' whether it exceeds the carrying capacity of the tires or not. Unless the tire equipment has an ample margin of safety, however, this attitude results in poor economy.

"The drawing of trailers, while more common abroad than in the United States, is another means of improperly loading tires. No doubt this is an economical means of hauling, but trucks so engaged are placing a greater strain upon their tires, and these should be at least the next size larger than those which would safely carry the truck without a trailer.

"Turning now to the effects of overspeeding on solid tires, I ask you to consider three things. They seem so axiomatic that they need only to be mentioned briefly. First, overspeeding generates excessive heat in the tires, which tends to shorten the life of the rubber. Even though not overloaded, they may be driven so fast that they are 'burnt up,' as it were, in a very short time. Second, it accentuates shocks and jars due to unevenness in the roadway. The stresses thus set up are really the equivalent of sudden overloads, and they tend just as effectively to cause the premature failure of the tires as though they were loaded beyond their capacity. Third, it induces the severe use of brakes, especially in thoroughfares in which there is much traffic. This in turn is apt to cause unnecessary friction with the road surface, which of course wears out the tires promptly.

"I am confining my remarks to the detrimental effects of these abuses upon the tires themselves, although our experience has been that they extend beyond the tires, and are only less injurious to the mechanism of the truck.

"Let us next consider who pays for these abuses. In guaranteeing the truck exclusive of the tires, the truck manufacturer conveniently arranges to 'step out from under.' The burden, therefore, seems to fall upon the truck owner or the tire maker, although I say frankly that the 'ultimate consumer' bears most of the load. When tires fail prematurely the truck owner looks to us for an adjustment. Generally our salesmen have an accurate knowledge of the conditions under which such tires are used, and, if they have been overloaded, we have taken occasion to warn the operator that we cannot be held responsible for failure to deliver normal mileage. Many users seem to feel that because their average loads do not exceed the rated carrying capacities of their tires they have not overloaded them, and consequently the rubber manufacturer should furnish other tires, free, to run out the guaranteed mileage. As there is no gauge by which the loads carried can be recorded, the tire maker has to accept the statement of the truck owner, or run the risk of an unpleasant controversy if he questions it. The truck is laid up—or perhaps merely the tire, if it is of the demountable type—and an adjustment or a paid renewal is made, prematurely. Either method of settlement is more costly than continued service under proper conditions. The truck owner complains that the cost of maintenance is higher than it had been represented to him, although the chances are he had not been impressed with the high cost of overloading.

"You will admit that it is not sound business for a manufacturer to replace an article without due charge, if the user of the commodity has wittingly or unwittingly destroyed it. In self protection, therefore, as well as for the education of the user, we stand our ground, and sometimes we have controversies through which we pay our share. We write letters, we send telegrams, we make personal calls and we send tires by express—all of which are expensive, and might have been avoided. Occasionally these contentions result in the loss of the customer, who decides to use another make of tire. In such cases we feel that we have merely transferred an undesirable account to a competitor, who takes up the burden. Sometimes, however, for the sake of future business under saner conditions, we pay our part of the bill at once as a matter of 'policy.' We make concessions which curtail the profit from the sale of the new tire, but, as most users realize the advantage of renewing with a larger sized tire, the business relations from that time on are upon a much more satisfactory basis.

"But you truck makers also pay, indirectly, because you sell fewer trucks than you might were it not for the unnecessarily high cost of maintenance which these abuses entail.. I venture to say that at this moment your sales departments are all spending time and money trying to overcome the honest conviction on the part of several prospective purchasers that the chief reason for their not buying trucks immediately is, not their unwillingness to make the original investment, but their fear that the cost of up-keep will more than offset the saving to be gained through the use of your trucks. And the chances are that their principal concern is over the cost of tires. This idea has gained undue prevalence because of the unfortunate experience of many operators who have been obliged to pay for destroying their own tires by overloading and over-speeding them, whereas, if they had used tires large enough to perform their work economically, they would be enthusiastic advocates of motor delivery.

"Frankly admitting the existence of these adverse conditions, how can they be improved or corrected? Primarily, by honest co-operation between the truck and tire maker. This very meeting is a good example of the sanest and most effective way to bring about better conditions. Realizing the nature of this problem and the necessity for tackling it vigorously and honestly, the B. F. Goodrich Company is distinctly grateful to be given this opportunity of discussing it with the most prominent American builders of motor trucks. And we shall welcome similar invitations to cooperate with you separately or as a body. We believe that by clearly and convincingly explaining the facts and the true economics of the situation, we can do much toward placing the industry upon a more sound and healthful basis. But we need your help. We need your influence through your written and verbal instructions to your agents, your demonstrators, and your salesmen, to abide by our schedule of carrying capacities, not because we arbitrarily say they must, but because if they do not they are injuring your business as well as ours. We need your help in teaching truck owners and operators that it is more economical to pay for larger original equipment than to buy smaller tires and then, knowingly or

Digitized by Google

unknowingly, destroy them prematurely. If we succeed in impressing this fact convincingly upon the purchasers of motor trucks, it will result in our mutual advantage, both in larger sales and a better satisfied clientele."

Valve Wear That May Cause Trouble.

It not infrequently happens that a carburetter that has been properly adjusted will give a bad mixture because of particles of foreign matter having interfered with the action of the auxiliary air valve spring, or lodging on the air valve seat. Sometimes the valve stem, working in a guide, will wear until there is a shoulder, which catches when the valve is opened more than usual, causing an irregular action of the motor.

Why the Crankcase Should Be Drained.

When the big end of the connecting rod is lubricated by means of the splash system, unless some sort of a baffle plate is interposed to prevent the greater part of the oil from reaching the piston, the under side of the piston soon becomes coated with a heavy deposit of carbon. It is essential, therefore, that the oil be drained out of the crankcase at frequent intervals and the case cleaned, for otherwise the carbon which drops, due to the vibration to which it is subjected and to the expansion and contraction of the piston, is ground up into a powder, and owing to its hardness acts as an abrasive.

"Seltzer Water" as a Fire Extinguisher.

A siphon of "seltzer water" makes a very formidable fire extinguisher for a small blaze, for not only can the stream be directed toward the center of the conflagration, but a considerable quantity of carbon dioxide is liberated from the liquid, which tends to smother the flames.

Wants and For Sale

15 cents per line of seven words, cash with order. In capitals, 25 cents per line.

MILESTONES

in the march of progress denote advancement and we who wish to keep abreast the times must certainly keep alive to the ever changing situations Otherwise we may soon be burdened with proverbial

MILLSTONES.

This is particularly true in respect to the purchase of automobiles, and many hundreds of people annually suffer the consequences of ill-advised purchases from firms that engage in re-selling cars that never should have been on the market. The moral is

INVESTIGATE

for yourself very carefully before you buy a car, and especially a second-hand car. It will no doubt interest you to learn what else we have to say on this subject. If so, write E. R. THOMAS MOTOR CAR CO., 1200 Niagara Street, Buffalo, N. Y.

EXTRA FINE Black Japan for enameling automobile lamps, radiators, fenders, etc. Will not crack, chip or peel. One coat covers solid. Air drying or baking. Have your dealer order today. THE COLUMBUS VARNISH CO., Columbus, Ohio.

AUTOMOBILE—Stoddard-Dayton. Address A. R. CAMPBELL, 31 E. Fourth St., Cincinnati, Ohio.

IF YOU are in need of an auto top, dust cover, slip lining or fore doors, write or phone F. P. MILLARD, Sharon, Mass.

AUTOMOBILE GARAGE, MACHINE SHOP, with stock supply stores, and living apartments; all complete, equipped up to date; on Long Island, near Amityville. Account family troubles must sell at once. Long lease; reasonable; good chance for party with $3,000. BOX 471, Farmingdale, L. I.

MAILING LISTS of automobile owners in Atlanta and several States. 303 Kiser Bldg., Atlanta, Ga.

BARGAIINS in new 4 x 5 4-cylinder auto motors. Equipped. F. E. ALFORD, Goshen, Ind.

FOR SALE—Half interest in an Automobile Garage and Repair Shop in one of the best towns of the Southwest. Best business in the city. A safe investment. Reason for selling—must get out in the open. For further particulars, BOX 202, care Motor World.

WINDSHIELD BARGAIN—Clear Vision Sprague Windshield. Folding type, extra heavy Sizes, 14" x 12" and 14" x 14", entirely new, all complete ready to put on your car—$10.00, cash with order. These windshields are all properly crated and packed and can be shipped at once. BROWN WINDSHIELD COMPANY, 1251 Woodward Ave., Detroit, Michigan.

WRITE AT ONCE if you want one or forty five-passenger touring car bodies at $10.00 each. BOX 35, Industrial Bldg., Indianapolis, Ind.

FORD OWNERS, ATTENTION! Equip your car with a Mello-Tone Auto Signal. Special for Ford cars. Sent on 10-day free trial. Price, $5.00. Express prepaid. ELECTRIC CITY MFG. CO., 65 Cherry St., Buffalo, N. Y.

FOR SALE—Model F Stanley steamer, cheap, $300. H. P. BEEBE, Fredonia, N. Y.

MAILING LISTS of Automobile Owners. S. H. CARROLL, JR., Albany, N. Y.

DAY UTILITY REMOVAL NOTICE—Having outgrown our old quarters at 812 Trumbull Ave., after April 1 office, factory and service garage will be located at 25 E. Milwaukee Ave., one-half block from Woodward Ave. Phone N. 881. DAY AUTO CO., Detroit.

FLANDERS 1911 4-passenger, used less than 90 days, $350. COLUMBIA AUTO EXCHANGE, 287 Edgewood Ave., Atlanta, Ga.

A TREMENDOUS SACRIFICE—A professional lady leaving city, indefinite period, will sacrifice Ranier 5-passenger 4-cylinder 30-H. P. touring car; top, folding windshield, high tension magneto, extra shoes, tubes, tools, etc.; $300; warranted perfect running order. MRS. STOUTENBERGER'S CAR, 1075 Intervale Ave., Bronx, two blocks from subway, New York City.

GASOLENE Rumble Seat Runabout; would make exceptionally fine truck; $100; also Cadillac Delivery Car, $100, running order. BINGHAM'S CHAUFFEUR, 1075 Intervale Ave., Bronx, near subway station, New York City.

WANTED—Ardsley touring car; state price and condition. C. H. CURTISS, Naugatuck, Conn.

LOZIER Touring Car, Model 7, 40 horsepower, good condition. JACOB HAGNER, 52 East Court St., Cincinnati, O.

AGENTS WANTED — To handle the $1000 G. J. G. "Junior," racy, classy and specially designed chaseabout with 104-inch wheelbase, with a real 26 H. P. motor, Bosch magneto, Dorian remountable rims with 32 x 3½ tires, at a price of $1,000, which is a money-maker for the sales agent. Write for literature and discounts to G. J. G. MOTOR CAR COMPANY, White Plains, N. Y.

QUALITY RUBBER CEMENT—Best in the World—Hotter the weather the better it sticks. For repairing automobile, motorcycle and bicycle inner tubes and tires. This cement is unequalled. Send 20c. in stamps for two sample tubes. For terms and discounts, write HENRY E. EBY, Fernwood, Del. Co., Pa

---

BARGAIN—$750 will buy a nearly new Mitchell 5-passenger automobile. New tires, Bailey tread, top, windshield and all accessories complete. Cost $1,500. As good as new, owing to short length of service. THE TRIUMPH ELECTRIC CO., Cincinnati, O.

GARAGE FOR RENT—Most prominent corner in Bergen section of Jersey City; entrance on two streets; floor space about 170 x 50 on ground floor, 100 x 50 on second floor; brick building with elevator. Apply to owner, T. W. LEAKE, Bergen Ave. and Montgomery St., Jersey City.

BROKEN CRANKSHAFTS, cylinders, crankcases, flywheels, gear teeth, pistons, perfectly welded and machined ready to replace. Guaranteed and references. Machinery up to 5 tons welded. ATLAS WELDING WORKS, 74-76-78 Irving St., Rahway, N. J.

HAVE a buyer for a good 1911 or 1912 auto in perfect shape; he will give his personal mortgage on good property for same at 6%. GEO. B. CLARK, Milford, Conn.

BROKEN CYLINDERS, crankcases, etc., made good as new by welding at about ¼ cost of new parts. No charge unless weld is satisfactory. Write for references and complete information. WATERBURY WELDING CO., Waterbury, Conn.

FOR SALE—5-passenger body, $30.00; top, $15.00; treads, 30 x 3½, $3.50; frame, $6.00; all kinds of repairs for Reo and Rambler cars at from one-half to one-fifth of the list price; also new and second-hand cars for sale. SCHISSEL AUTO CO., Cherokee, Iowa.

EXPERT CHAUFFEUR, motor boat operator and repair man wants work at once. Sober and reliable. Seven years' experience. Address, BENJ. SPRAGUE, 55 High St., Claremont, N. H.

PALM GUM Tire Seal prevents punctures and will keep air from escaping even if punctured by 20-penny nails. Life of tire prolonged. Cost about $10 on average car. Weighs about 20 lbs. Ask your dealer to get it for you. If he won't furnish it we will, at $5.00 per gallon—25% with order. PEORIA AUTO & SUPPLY CO., Sole Distributors, Peoria, Ill.

ELMORE TOURING CAR, 1911, fully equipped, extra tires, warranted fine condition, like new, great roadster, price $750, act quick, send for full description. H. J. DANIELS, Norwich, N. Y.

SCORED CYLINDERS repaired, $12 each. No enlargement of bore—no need for new pistons and rings. Send piston with cylinder. Absolutely reliable method. Better investigate and save money. References, testimonials, and full details on request. WATERBURY WELDING CO., Waterbury, Conn.

ACETYLENE SELF-STARTER, $12.50—Fully guaranteed, easily installed on any car with dual ignition in two hours. Money back if not satisfied. Booklet free. THE MOORE & BOWES CO., Battle Creek, Mich.

AUTOMOBILE SPECIALTIES—Models and experimental work, electrical and mechanical, special auto parts, bearings, etc. AUGUST HORMEL, 587 Hudson St., New York City. Tel. 2873 Chelsea.

SALESMEN, one who is now visiting automobile trade or owners. Good money made on a very attractive proposition. STURDY MFG. CO., 2637 Michigan Ave., Chicago, Ill.

LOCOMOBILE—Forty horsepower. Special bargain for anyone wanting a first-class high grade automobile. In first-class condition. Full equipment including fore door torpedo body, nickel trimmings, top, Warner Odometer, Prest-O-Lite, Klaxon, shock absorbers, seat covers, Kellogg air pump, tire trunk, Rushmore headlights, combination electric and oil lamps. 100 Wright St., Newark, N. J.

1,004,635. Starting Device. Wilber R. Dunkel, Pana, Ill., assignor of one-half to Carter R. Scoggin, Harristown, Ill. Filed Dec. 12, 1910. Serial No. 596,863.

1. In a starting device for gas engines, the combination with a ratchet wheel fixed on the engine shaft and having conical ends; of a drum comprising a cup-shaped body having in its bottom a hole for said shaft and a bearing face adapted to rest on one of said ends, and a plate threaded into the mouth of the cup and having a central hole for said shaft and a bearing face adapted to rest on the other of said ends, the plate having a series of perforations through it, a lug cast within the rim of the body and having a threaded hole, a screw passing through the bottom of said body and screwing through said hole and having a reduced tip engaging one of the perforations in said plate to hold the latter in adjusted position, a pawl pivoted on the body of the screw with its tip directed toward said teeth, a spring pressing the tip toward the teeth, manipulating means for directing the rotation of the drum in one direction, and retracting means for normally rotating it in the other direction.

1,004,636. Starting Device. Wilber R. Dunkel, Pana, Ill., assignor of one-half to Carter R. Scroggin, Harristown, Ill. Filed Dec. 12, 1910. Serial No. 596,864.

1. In a starting device for gas engines, the combination with a housing extending across the main shaft, a bar slidable within said housing and having teeth on its lower edge at its central portion but omitted at its end portions, a toothed wheel on the main shaft of the engine with which said teeth on the bar are adapted to engage, a retracting device at the inner end of the housing connected with the inner end of the bar, and manipulating means connected with the outer end of the bar and leading to within reach of the operator; of means for permitting the teeth on the rack bar to engage those on the wheel when the former is drawn forward and for mechanically disconnecting them when said bar is retracted.

1,004,642. Rubber Tire. George H. Gillette, New York, N. Y. Filed Nov. 28, 1910. Serial No. 594,517.

1. A rubber tire comprising a plurality of sections of resilient material, and an externally mounted retaining ring, said tire having a greater number of said sections than normally required to form a continuous circle of the diameter of said retaining ring whereby the said sections are held in place in a compressed condition.

1,004,667. Vehicle Wheel. Louis B. Lodge, Cuyahoga Falls, Ohio. Filed Sept. 3, 1909. Serial No. 516,016.

A vehicle wheel comprising a hub; spokes attached at their inner ends to the hub and arranged radially, which spokes are tubular from their outer extremities a suitable distance inwardly; a rim extending circumferentially of the wheel at the outer ends of and attached to the spokes, which rim is concentric relative to the hub; a tire; a tire holder extending circumferentially of and concentric relative to the rim and shiftable vertically in a plane arranged at a right angle to the axis of the wheel, said tire holder having an interior chamber extending circumferentially of the tire holder, which chamber has its inner circumferentially extending wall provided adjacent each spoke with a bolt-hole which is elongated circumferentially of the tire holder; a bolt having its shank arranged within and longitudinally of the tubular portion of each spoke and extending through the adjacent bolt hole in the tire holder, which bolt has its head overlapping the inner surface of the inner circumferentially extending wall of the aforesaid chamber between the said bolthole and the side walls of the chamber, and a spiral spring mounted and confined on the said shank and acting to retain the tire holder concentric relative to the wheel rim.

1,004,695. Automobile Tire. Charles E. Scheuring, West De Pere, Wis. Filed Mar. 10, 1911. Serial No. 613,488.

1. In a device of the class described, a felly; a tread plate; parallel superposed, reversely curved inner and outer springs disposed circumferentially of the wheel, the ends of the outer springs being disposed adjacent the tread plate, and the ends of the inner springs being disposed adjacent the felly; fixed members upon the tread plate constituting an abutment for the adjacent ends of adjoining pairs of outer springs; and fixed members upon the felly constituting an abutment for the adjacent ends of adjoining pairs of inner springs.

1,004,696. Internal Combustion Engine. Ralph Schoeck, Oerlikon, Switzerland, assignor to Schweizerische Werkzeugmaschinenfabrik Oerlikon, Oerlikon, Switzerland. Filed Apr. 12, 1911. Serial No. 620,650.

1. In a rotary combustion engine, the combination with a cylinder having an exhaust port, an inlet for combustible, and an air inlet port all located proximate the periphery of the cylinder and an air inlet, and a delivery passage proximate the center of the cylinder; of a drum mounted to rotate within the cylinder eccentrically, and pistons passing through the drum to the cylinder wall moving with said drum, and forming walls of combustion chambers between the cylinder and drum, and walls of compressor or pump chambers within the drum, the combustion chambers co-operating with said ports and inlet proximite the periphery of ht ecylinder and the pump chambers with said passages proximate the center of the drum.

1,004,703. Vehicle Wheel. Lonnie C. Smoot, Hillsboro, Tex. Filed July 15, 1910. Serial No. 572,124.

1. A mechanism consisting of a plurality of radial rods, means being provided to guide each rod under radial displacement, a coiled spring mounted upon each rod, the outer extremities of which will move with the rod, while the inner extremities remain stationary, the outer extremities of each rod being connected by a pair of links with the inner extremities of the two adjacent rods.

1,004,720. Internal Combustion Engine. William Morten Appleton, Weston-super-Mare, England. Filed Apr. 15, 1911. Serial No. 621,264.

1. In an internal combustion engine of the two-cycle type, the combination of three pairs of cylinders one of each pair being a power cylinder and the other a displacer cylinder, compound pistons working in said cylinders, an inlet port in each power cylinder, a gas by-port in each power cylinder, a passage in each power piston adapted to put the inlet and gas by-port into communication during a predetermined part of the stroke of said piston, a by-pass port in each power cylinder for admitting the gas from the displacer cylinder, an exhaust port in each power cylinder, a distribution port in each displacer cylinder, and distribution passages each connecting the gas by-port of the power cylinder of one pair, the by-pass port of the power cylinder of another pair, and the distribution port of the displacer cylinders, the arrangement of said ports and passages being such that in action the displacer cylinder of each pair draws its gas through the piston of the power cylinder of one of the other pairs and delivers it into the power cylinder of the third pair.

1,004,733. Automobile Brake. William Besler, Colma Station, Wis. Filed Feb. 18, 1910. Serial No. 544,698.

1. In a vehicle brake, the combination of a shoe adapted for engagement with the ground, a swinging leg pendent from the vehicle and having the shoe pivotally connected to the lower end thereof, the said leg being normally swung upwardly and forwardly to hold the shoe in an inoperative position, a forwardly extending brace rod pivotally connected at its extremities to the shoe and some stationary part of the vehicle, the said brace rod being longitudinally extensible and being formed in sections which are yieldably connected, the rear end of the brace rod being hinged so as to fold back upon itself when the leg is swung upwardly to hold the shoe in inoperative position, and means for normally holding the shoe in inoperative position.

1,004,738. Ball Bearing. Fred Eugene Bright, Philadelphia, Pa., assignor to The Hess-Bright Manufacturing Company, Philadelphia, Pa., a Corporation of Delaware. Filed June 1, 1906. Serial No. 319,782.

1. In a ball bearing comprising two bearing rings having races of curved cross section and balls in the races, a homogeneous anti-friction metal separator interposed between two adjacent balls, the separator extending somewhat into the ball races.

1,004,739. Process of Assembling Ball-Bearings. Fred Eugene Bright, Philadelphia, Pa., assignor to The Hess-Bright Manufacturing Company, Philadelphia, Pa., a Corporation of Delaware. Filed Oct. 15, 1909. Serial No. 522,824.

1. The process of assembling a ball bearing comprising bearing rings, balls and separators, the latter being each composed of malleable metal capable of easy deformation and of solid cross-section, consisting in originally forming the separators so that they may be readily inserted between the rings, inserting the separators in working position between the balls, and thereafter changing the form of the separators so that they are prevented from displacement from working position.

1,004,816. Automobile Fire Engine. John Livingston Poultney, Haverford, Pa., assignor to James Boyd & Brother, Inc., Philadelphia, Pa., a Corporation of Pennsylvania. Filed June 24, 1910. Serial No. 568,651.

In an automobile fire engine the combination of a shaft, a change speed mechanism for driving the shaft at different speeds, the differential-and-brake sleeve driven by said shaft at different speeds, a wheel-driving gear driven by said shaft, a pump, means interposed between the pump and sleeve for driving the pump, and devices for connecting and disconnecting said shaft and

Digitized by Google

wheel-driving-gear and said sleeve and pump, substantially as described.

1,004,819. Vehicle Wheel. Ernest Louis Reguin, San Francisco, Cal. Filed May 11, 1910. Serial No. 560,596.

1. In a vehicle wheel, the combination with a hub, of inner and outer separated rims, spokes on the hub sppporting the inner rim, said spokes being recessed on one side from their outer ends to a point terminating short of the hub, said inner rim comprising a channel ring divided circumferentially into two sections, one of which sections is in the form of a removable flanged ring substantially Z-shape in cross section, and having one of its flanges fitting the recessed portions of the spokes, and the other section of said channel ring being integral with the spokes, the outer rim formng a complementary channel of larger diameter than, and slidably embracing the inner channel ring, and having a removable member on the same side of the wheel as the removable flanged ring of the inner rim, and overlapping said ring, and an inflatable tube housed between said channels.

1,004,820. Vulcanizing Apparatus. Benjamin P. Remy and Frank I. Remy, Anderson, Ind., assignors to the Remy Electric Company, Anderson, Ohio, a Corporation. Filed Apr. 29, 1909. Serial No. 492,853.

A vulcanizing mold having a plurality of mold members arranged with reference to each other to form a rubber chamber from which the rubber cannot escape during vulcanization and so that the compressing movement of said members will not be limited excepting by the rubber, rods extending through all of said mold members, and springs on said rods acting against said mold members for compressing the same.

1,004,833. Combined Muffler Cut-out Valve, Whistle, and Safety Alarm Valve. Henry Grady Weaver, Eatonton, Ga. Filed Aug. 20, 1910. Serial No. 578,131.

1. In apparatus of the class described, the combination of a valve casing having a discharge opening provided with an inwardly contracting portion forming a valve seat, said valve casing being also provided with an outlet opening for connection with the exhaust pipe of an internal combustion motor, a rod mounted for vertical movement in, and through the casing, a valve on the said rod, a spring acting on said rod to normally close said valve against the said valve seat, and a whistle bell disposed exteriorly of the said valve casing, attached to the said rod, at a point spaced from the valve, and movable with said rod, and said valve.

1,004,887. Automobile Gun Mount. Samuel N. McClean, Cleveland, Ohio, assignor, by mesne assignments, to The Automatic Arms Company. Filed Nov. 10, 1906. Serial No. 342,864.

1. In a vehicle in which the body is supported from an axle by interposed resilient means, interlocking means carried by the body and axle normally held out of engagement by the resilient means, and means carried by the body for compressing said resilient means to bring said interlocking means into engagement.

(Reproduction of Front Cover of our 1912 Annual Catalog which is printed in three colors.)

OUR 1912 CATALOG

the Largest and Most Complete Catalog of the kind, containing 256 Pages, is Now Ready for Distribution. The Circulation is Limited to ONE HUNDRED THOUSAND Copies. It will be mailed to any one on request.

Cut Prices

Concerns that offer Large Discounts make it their practice to INFLATE LIST PRICES and then offer Large Discounts, which are somewhat misleading. We have seen a catalog in which a certain spark plug is illustrated, "PRICE $2.50, OUR PRICE $1.00," while THE STANDARD LIST or RETAIL PRICE for the same spark plug as illustrated in OUR 1912 ANNUAL CATALOG and advertised by the manufacturers is $1.00 each. Their CUT PRICE therefore Is Not Lower Than OUR LIST PRICE.

Don't Be Deceived by Large Discounts

Quoted from Inflated List Prices

Speaking of pneumatic tires, air is air, but you can't say the same of rubber—

still less can you say it of the rubber composition of which tires are made, which to most people simply means rubber. There is a wide choice in brands of tires, and extravagant claims can easily be made, but — After all, the worth of a tire depends upon two things, viz.: A **knowledge** of rubber and a real **desire** to make good tires. The mileage average of

Kelly-Springfield Automobile Tires

—better by a thousand or two than that of the average tire—shows our **knowledge** of rubber. The reputation that you have known since 1895 shows how our **desire to make good tires** has been lived up to. Let these be your guide posts in tire buying.

Tire Troubles Are Impossible With This Airless Tire

It is not the puncture that stops your car. It is the result of the puncture—the collapsing of your punctured pneumatic tire—that lays your car up on the roadside, or sends it to the shop for repair, wasting your time and money.

Now, resiliency is no longer dependent on inflation. A few years more—and inner tubes, pumps and tire troubles will be things of the past for every motorist. The question that concerns you is—Will you be one of the fortunate first or one of the money-drained last to get free of tire troubles?

The Dayton Airless Tire Has Proved Itself Absolutely Trouble-Proof

Yet it rides with all the ease of a pneumatic. Its equal resiliency with properly inflated pneumatics has been proved by engineers' scientific tests and by thousands of users, in actual service. No one riding on Dayton Airless Tires, for the first time and without being told, ever dreams that he is not riding on pneumatics. Ask us to give you proof. We'll do it.

Dayton Airless Tires are constructed inside of soft, cushiony rubber columns alternating with spaces of free —not compressed—air. These columns give, under contact with obstructions—expand into the air on each side but do not rebound after passing over. The Dayton Airless Tire gently lifts you over obstructions instead of throwing you over.

You can see that this construction is trouble-proof. Blowouts, punctures, leaks, all tire troubles, are impossible. You want all the information about this wonderful tire—all the facts proved by over three years' service on thousands of cars—the proofs of its economy, its ease on the mechanical parts of your car, its durability, its wearing service.

So write us today for the free book—"The Air-Free—Care-Free Tire." It answers your every question.

Mr. Automobilist:

Your tire maker is very anxious to impress upon you the importance of

Tires Inflated to the Right Pressure

He insists that this is tire economy and

Saves You Money

How do you know what pressure you have in your tires? A

SCHRADER
UNIVERSAL
Tire Pressure Gauge

(Trade Mark Registered in U. S. Patent Office)

(Patented March, 1898—Other Patents Pending)

will tell the exact pressure in your tires at any time, day or night, by simply holding this Gauge to your Valve for a second. Its recording sleeve remains in place, showing the exact pressure in the tire so that the Gauge can be taken anywhere and read, at night to the front of the car into the light of the lamps. After the pressure has been ascertained the Indicating Sleeve can be pushed back into the Gauge with your finger. No catches or snaps to operate or get out of order. This Gauge is 2½ inches long over all, short enough to apply easily to the smallest diameter of wheel and can easily be carried in the vest pocket or the change pocket of your trousers.

AJAX
TIRES

(Guaranteed 5000 Miles)

Strong Selling Talks for Ajax Dealers

The real test of a tire is in long, rough road usage, as most motorists are tourists and not track racers. In recent years Ajax Tires have been the winning tire equipment in more reliability and touring contests than any other make of tire.

This is the highest possible recommendation a dealer can give a tire because it means that such a tire is exactly suited to the usage of his average customer. Ajax Dealers find that it is a sales-clinching point.

Ajax Dealers are entitled to the cream of the trade and they get it! Write for Ajax Dealer inducements.

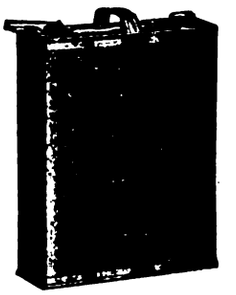
Polarine

The Best Oil for All Motors

When a car starts out lively in the morning and then shows signs of sluggishness later in the day, it usually means something is wrong with the lubrication.

Use **POLARINE** Oil and you will avoid two-thirds of all motor troubles.



POLARINE is the best automobile oil yet produced.

It gives the maximum lubrication for the amount used. It insures the least possible friction and wear, with full compression and power.

It leaves no carbon deposit.

It feeds freely right down to zero.

Look for the flat, convenient can —just fits in the tool-box. Ask your dealer.

Our free booklet tells all about the Polarine Brands, and contains many useful hints on the care of a car. Write for your copy today to any agency.

Standard Oil Company
(Incorporated)

YOU DO

want a smooth-running motor, don't you?

Equip your motor with a set of "AC STAR" spark plugs and you will be able to run at top speed and throttle down with no danger of back-firing, as the superior design of "AC STAR" plugs prevents pre-ignition.

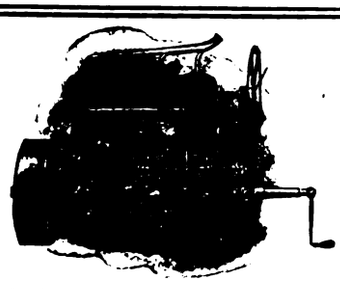
Cutting CARS

Get Posted

See our free Table of Comparative Motor Car Values — It will make you a posted purchaser and enable you to form an estimate in your selection of a car that is conservatively the most for the money. **Cutting cars cost less per Horsepower and per Wheel Base Inch than any other automobile selling for $1200 or more.** In point of design, workmanship and finish they are equal, and in some cases superior, to cars selling for from $3000 to $4000.

The Cutting catalog mailed anywhere on request.



CLARKE-CARTER AUTOMOBILE CO.
Jackson, Michigan

If there is no PULLMAN agency in your territory let us hear from you at once. Our 1912 line includes the famous PULLMAN "4-30," "4-35," "4-50" and our two big leaders, the "4-40" and "6-60." The equipment includes self cranking motor, electric lighting device, top, windshield, speedometer, foot and robe rails, etc.

PULLMAN cars "lead the leaders." Some of our agents sell as many as 200 PULLMAN automobiles each year. Let us put you in touch with our agents and find out for yourself why PULLMAN agents are always good agents.

"OUR OFFER"—If there is no PULLMAN agency in your territory we will arrange to "show you" at absolutely no expense to you.

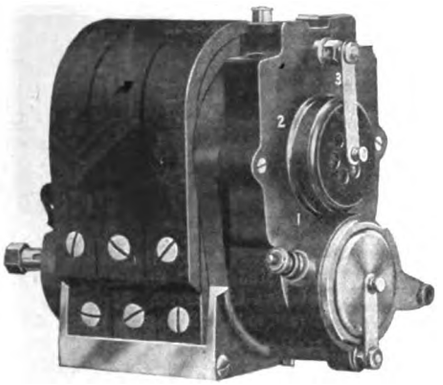
B & L CASTER FRONT AXLE
Makes a Big Winner in Philadelphia
Our Philadelphia Agent writes it is a Great Success.

A. S. BURNELL, President and General Manager,
1346 Michigan Avenue, Chicago, Ill.

Philadelphia, Pa., February 28, 1912.

Dear Sirs:—The axle is a great success, is running fine. Have made several demonstrations and every one says it's the only front axle that ought to be allowed to go on the automobile, for safety, easy steering and perfect control. Will sell the majority of those I have demonstrated for. Enclosed you will find order for one axle to go on a Studebaker car, 1908 model, more orders will follow later. Send us a big cut for we are going to run a one-half page in our newspaper, we will advertise it right. We will equip at least one thousand cars this year. Our new garage will be at 1907 after March 12th, N. 23rd St. Circulars received all O. K., thanks for same. Rush the order for axle, as every one on a car will sell several more. Yours very truly,

H. SCHROEDER,
President and General Manager Lake Schroeder Auto Exchange.



Philadelphia, Pa., 1418 Blavis St.

AGENTS WANTED for all cities in the United States to put the B & L Caster Front Axle on old cars. Exclusive territory given to good men. Our axle when on a car proves that it is the only safe axle made. In buying a new car demand that it be equipped with the B & L Caster Axle. Write for Agency Proposition. Address:

A. S. BURNELL, Manager Chicago Branch, 1346 Michigan Avenue.

"The Horn that's Made for the Discriminating"

TUTO HORN

THE TWO TONE HORN

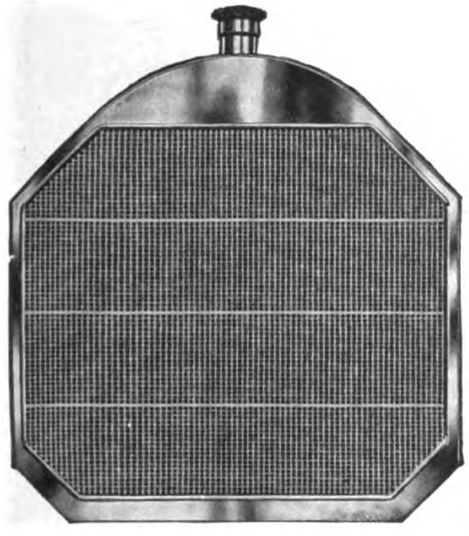
Warning Signal Problem Solved.

THE TUTO horn has solved the warning signal problem for the public, the car owner and the car manufacturer, by providing two separate signals, a low one for all ordinary purposes (replacing the bulb horn) and a loud note for emergency or for use when the low note fails to attract instant attention.

¶ The TUTO horn produces these two distinct signals by the use of one horn, one button, one cord and one battery and the completeness of the fixtures make it possible to have a neat and most reliable job of installing, which is devoid of troubles and insures constant operation.

¶ The special TUTO fixtures make it possible to place the button on the steering wheel, right under the thumb so as to be operated without any effort on the part of the driver.

¶ An ordinary pressure on this TUTO button produces the low-abrupt-tone, which warns effectively, fully 90 per cent. of the time. A further or complete pressure on the same button instantly gives the loud-abrupt-tone which is sufficiently strong to demand attention under extreme conditions of traffic or travel.



¶ The TUTO is the only horn with the "two-tone" feature, the only horn coming complete with special fixtures to make a permanent and neat installation, and therefore it is the only logical signal for standard equipment for any motor car.

Timken Roller Bearings Have Led the Way in Satisfactory and Economical Service

They were born before the first motor car—way back in the horse age. They gave satisfaction in the earliest motor cars. They are giving satisfaction today in more than a quarter of a million pleasure and commercial cars.

Because they are right in principle.

TIMKEN
BEARINGS & AXLES

Timken Bearings in a Motor Car
Improve Service and Reduce Upkeep

The way to strong, safe, satisfactory axle-construction was blazed by Timken.

The one-piece, pressed-steel housing which adds wonderfully to rear axle strength was introduced by Timken.

The "unit" power-transmitting plant in rear axles—so easy to get at—is a Timken contribution which has lowered upkeep cost.

The grinding of gears by special Timken-designed machines that remove all the minute inaccuracies left by the finest gear-cutting machines—is exclusively Timken, and makes for smooth, quiet running.

Timken leadership in axles is due to an immense organization of experienced, able, loyal men whose sole object in life is to make axles of the highest possible quality.

To know Timken-Detroit axles is to have a higher appreciation of the wonders of motor-car construction

Timken Bearings improve service because they are so designed that they do to the best advantage ALL the things which the bearings in a car must do.

They reduce friction loss to almost nothing.

They carry heavier load in proportion to their size—because they carry it along the whole length of rollers, not on the points of balls.

They meet side pressure or "end-thrust," because the rollers are tapered and revolve at an angle to the shaft.

They show almost no wear—because the load is evenly distributed over a large enough area of contact.

Therefore they meet and take up the shocks, strains and stresses of travel.

They keep the wheels from wobbling.

They keep shafts perfectly aligned and gears in mesh—insuring perfect transmission of power.

Timken Bearings reduce upkeep because they last longer and do not have to be replaced.

This is, first of all, because they wear so little.

It is also because even that slight wear can be wholly taken up by adjustment—by advancing the cone into the cup.

Perfect adjustment is possible because all the surfaces are tapered and after adjustment meet in straight lines just as they did before.

The perfect alignment is assured in two ways:

By a pressed steel "cage" that guides the rollers on the cone.

By the *two ribs on the cone* that hold the alignment of the rollers when under load.

Non-adjustable bearings steadily give worse service, till at last they are beyond help and must be replaced bodily.

Timken Tapered Roller Bearings of proper size, properly mounted and properly cared for, outlast the car, and give continuous good service.

(Reproduction of Front Cover of our 1912 Annual Catalog which is printed in three colors.)

OUR 1912 CATALOG

the Largest and Most Complete Catalog of the kind, containing 256 Pages, is Now Ready for Distribution. The Circulation is Limited to ONE HUNDRED THOUSAND Copies. It will be mailed to any one on request.

Cut Prices

Concerns that offer Large Discounts make it their practice to INFLATE LIST PRICES and then offer Large Discounts, which are somewhat misleading. We have seen a catalog in which a certain spark plug is illustrated, "PRICE $2.50, OUR PRICE $1.00," while THE STANDARD LIST or RETAIL PRICE for the same spark plug as illustrated in OUR 1912 ANNUAL CATALOG and advertised by the manufacturers is $1.00 each. Their CUT PRICE therefore Is Not Lower Than OUR LIST PRICE.

Don't Be Deceived by Large Discounts

Quoted from Inflated List Prices

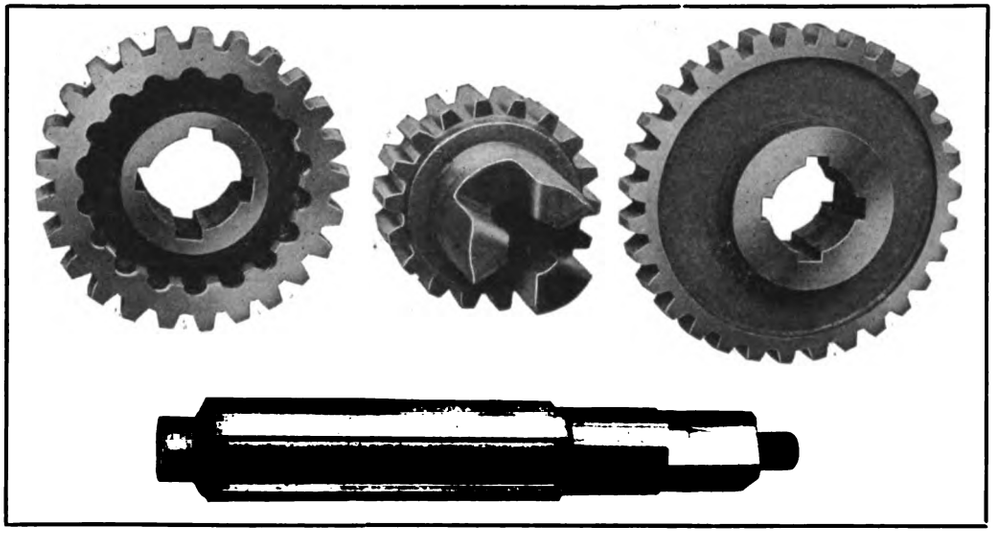
Remy Electric Co.,
1926 Broadway,
City.

Gentlemen:-

It affords us pleasure to testify to the efficiency of your service department. Your evidently increased desire to see that the Remy magneto gives satisfaction to customers, backed by your ready support in overcoming complaints and making adjustments cannot fail to rapidly establish the Remy magneto in the confidence of most manufacturers and owners of automobiles.

Yours truly,

J. I. Case Threshing Machine Co.
Branch House Manager.



Did you ever hear of Ignition Service before the Remy Electric Company created it?

Are you taking advantage of this Remy Service, making it a valuable part of your complete car service?
Let us tell you more about the The Best Magneto and Real Magneto Service.

The first *definite* guarantee of *actual* mileage ever given on tires, now goes with all

PENNSYLVANIA VACUUM CUP TIRES

Three factors are making these tires the stellar attraction in the trade for 1912

The 4,000-mile actual and definite guarantee attached to every tire.

The unique guarantee that the vacuum cups *will not* skid on slippery pavements, or full price refunded.

And lastly, the tremendous demand for tires providing a dependable standard of practical and satisfactory service.

Prices, terms and all information supplied you immediately.

Hupmobile

Long Stroke "32" Touring Car—$900

F. O. B. Detroit, including equipment of windshield, gas lamps and generator, oil lamps, tools and horn. Three speeds forward and reverse; sliding gears. Four cylinder motor, 3¼-inch bore and 5½-inch stroke; Bosch magneto; 106-inch wheelbase; 32 x 3½-inch tires. Color, Standard Blue.

Not the Price; Not the Specifications; But—the Name Added to Both

You would do this car **less than justice** if you judged it by its price.

You would **fail to do it full justice** if you judged it by the generous specifications.

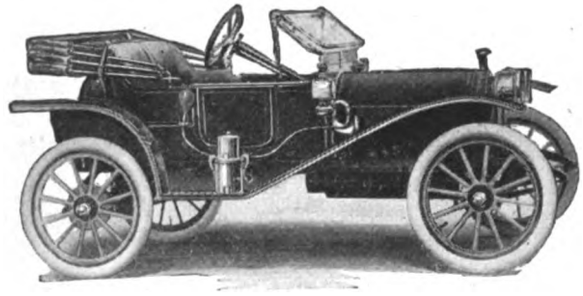
It is what the car has always stood for, that renders the price remarkable.

It is the Hupmobile record; and the Hupmobile reputation; that emphasize the extraordinary character of the specifications.

The price is not, in itself sensational—but the high standard of Hupmobile practice, at that price, **is** sensational.

You do not sell certain large cars of highest price because they boast a longer wheelbase; or more generous proportions in any part of the chassis.

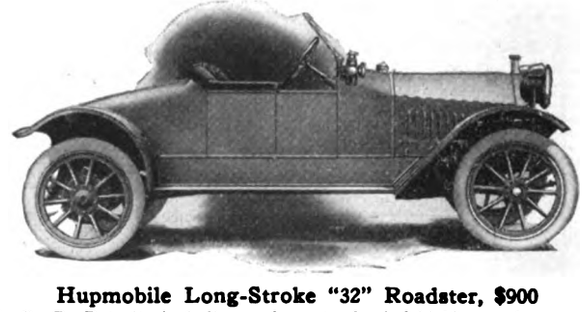
You sell them because their name and their word have always been synonymous with service and worth.



And, in its class, the Hupmobile has always held its ideals as high as cars of the highest worth.

It has shown itself worthy of a place beside them—worthy to share the same garage; it has fulfilled its mission as efficiently as they fulfill theirs.

Bear these things in mind as you study the cars in detail—then, and not till then, will you fully realize the remarkable value embodied in the price and in the specifications.

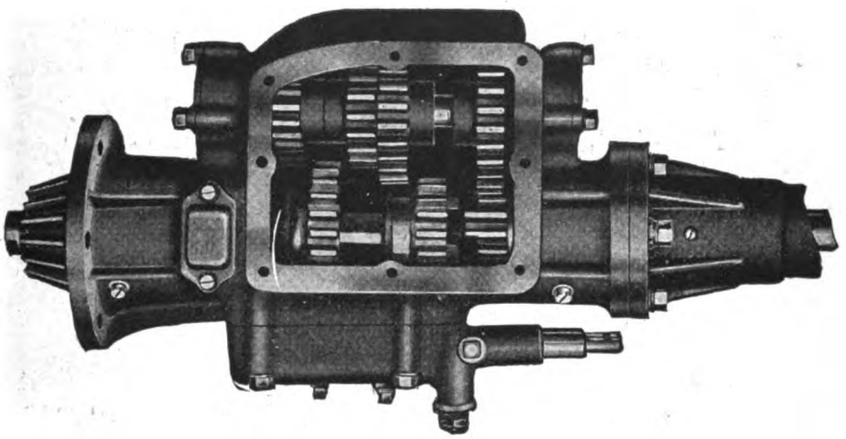


We are quite willing that you should compare this new Hupmobile with cars which sell for several hundred dollars more.

We will cheerfully abide by your decision, if it does not demonstrate either equality or superiority in any definite and positive test which you may designate.

Standard 20 H. P. Runabout, $750

F. O. B. Detroit, with same power plant that took the world-touring car around the world—4 cylinders, 20 H. P., sliding gears, Bosch magneto. Equipped with top, windshield, gas lamps and generator, oil lamps, tools and horn. Roadster, 110-inch wheelbase, $850.



Hupmobile Long-Stroke "32" Roadster, $900

F. O. B. Detroit, including quipment of windshield, gas lamps and generator, oil lamps, tools and horn. Three speeds forward and reverse; sliding gears. Four cylinder motor, 3¼-inch bore and 5½-inch stroke; Bosch magneto; 106-inch wheelbase; 32 x 3½-inch tires. Color, Standard Blue.

COVERT

Simplicity of construction, durability, and high efficiency are the three best selling points of the COVERT UNIT TRANSMISSION PLANTS.

Think of the saving of cost in assembling by reason of the simpleness of the construction. Think of a transmission, the gears, shafts and bearings of which are made of nickel steel, carbonized, heat treated and ground to accurate measurements. Think of high efficiency produced by concentration of effort on one particular product.

Think of Covert Unit Transmission Plants embodying these three points and many more of great importance to the Truck Manufacturer and then allow us to go over your Transmission problem with you.

Sounds Like An Irish Bull

We charge the *least* for the Stewart Speedometer because it's the *best* speedometer. Sounds like an Irish Bull, doesn't it? But the argument is sound.

The better an article the better it pleases users. The better it pleases users the larger its *sale*. The larger its sale the less the cost of *producing* it. For the oftener a machine is used the less is the machine charge on each part it makes.

A smaller *cost* makes a bigger demand—and a bigger *demand* makes it easier to install *still* faster and *better* machinery.

That's the story of the Stewart Speedometer. That's why we can afford to make the finest speedometer on earth and ask the least for it.

It's the best ever *known;* but the *price* hasn't grown.

Not an *aristocrat*—it *works.*

Speedometers, $15 to $30
Rim Wind Clock Combinations, $45 to $70

Magnetic principle—jewel bearings—wearing parts hardened and polished; open dial—large figures, easily read—absolutely accurate; 100,000-mile season odometer, 100-mile trip register, can be reset to any tenth of a mile. Guaranteed for five years. Strongest flexible shaft—drop forged swivel joint—noiseless gears.

"ALWAYS ON THE JOB."

The Stearns-Knight Car

The Vital Point

Remember that the engine is the heart of your car. All else is of minor importance.

So the points discussed here overshadow all others, if you want a modern car.

They call for your attention.

10,000 Cars

Have Knight-Type Engines in Them

These cars bear names which stand the world over for the utmost in automobiles.

They were built by engineers who have always led in this industry.

They are owned by men who demand the best.

These 10,000 cars—the greatest cars in existence—have proved that Knight-type engines are the coming type.

Daimler—England's foremost car—controls the British rights. That has been a Knight-type since 1908, and its sales have quadrupled since then.

Mercedes controls the German rights. Panhard for France, Minerva for Belgium.

Thus the master engines of the world have been displaced by Knight-types.

A Knight-type engine won the Dewar Trophy in the greatest engine test on record.

It won the Scottish Economy Trophy. It holds world records on points that count for most.

That's why we adopted it for the Stearns-Knight, after two years of rigorous tests.

"Wait and See"

Makers of poppet-valve engines say, "Wait and see."

But the Knight-type is six years old. Daimler has used it since 1908.

One after another, the greatest makers in Europe have been forced to pay royalty for it. It is used now in 17 famous makes of cars.

Some $25,000,000 has been already invested in Knight-motored cars of the highest grade.

And the demand for Knight-type cars today is three times the possible output.

How much longer is it wise to wait? We waited three years after Europe came to it. We were not willing converts.

But we know when progress can't be longer stopped. The cars of the future will be Knight-type cars.

We were compelled by the evidence—as you will be—to come to this type of car.

Like Coasting

It is almost like coasting all the time to ride in a Stearns-Knight car.

The silence is almost uncanny.

No valves to pound open, no valves to spring shut—hundreds of times a minute.

No cams to grow noisy, no timing gears to hum.

No valves to grind. No carbon to cause leakage.

There is luxury of motion in a Stearns-Knight, known in no old-type car.

It's like gliding on the road. All the evidence of effort to which you are accustomed is lacking in this car.

There is wondrous flexibility. There is that continuous power for which electric motors are famous.

And the engines grow better with use. They show more and more power. We have Knight-type engines run for six years which are as quiet and efficient as when new.

Equipment

Warner Auto-Meter, Model K.
Banker Windshield.
Silk Mohair Top and Cover.
Vesta Dynamo Electric Lighting System.
Continental Q. D. Demountable Rims (two extra rims).
Klaxon Horn—also Bulb Horn.
Trunk Rack, Robe Rail, Foot Rest, etc.

Touring Car
Toy Tonneau
Roadster
$3,500

One-Half More Power

Stearns-Knight engines are rated on the poppet-valve basis.

But we guarantee the engines to show at least 50 per cent more than the rated power.

This is due in part to the spherical firing chamber. It is mostly due to the saving of leakage.

Poppet valves are rarely tight. When carbon accumulates the waste of power is enormous.

Judge for yourself what this saving means during the life of a car.

These are advantages too great to be disregarded.

The greatest engineers have had to adopt them. And most of the others are now seeking ways to end the poppet valve.

The time is fast coming when all high grade cars must have a new-type engine.

A Costly Change

Engineers have spent over $1,000,000 in perfecting the Knight-type motor.

We have ourselves spent $200,000, plus two full years, to meet American requirements.

Then this engine requires far more careful construction in every detail of the car.

Noises which were drowned by the old-type motors show up with the Silent Knight.

So this innovation was costly.

But our sales have doubled since the Stearns-Knight came out. They have compelled a new factory. At times our output was three times oversold.

This multiplied demand makes the Stearns cost less than any other Knight-type in America.

Hundreds Know

Hundreds of Stearns-Knight cars, in the hands of owners, have covered thousands of miles of road. The owners are men who know cars—men who demand the best.

The letters we get from them form the highest tribute ever paid to an American car.

The facts which won them will win you when you know them. They are the same facts which won 10,000 buyers in Europe.

They are irresistible to any man who wants the utmost in a car.

The Future Type

The evidence is that the leading cars of the future are bound to be Knight-motored cars.

History shows that what Daimler, Mercedes and Panhard adopt will soon mark the best cars the world over.

In buying a car for years to come, this fact should be well considered. You want the coming, not the passing type.

In two more years Knight-types will be common among high grade cars—as in Europe now. Today the Knight-type, in its perfection, means in America a Stearns-Knight car.

Go See This Car

Go to your local dealer and see this Stearns-Knight car.

But first write for our books. Get all the facts. Then judge for yourself if Knight-type is the future type.

Write now for these books. The Stearns-Knight car is the topic of the year in Motordom. Cut out this coupon, mail it to us, and we'll send all the interesting facts.

There Is Only One "INNERSHU" The Genuine Bear This Mark

"INNERSHU"

TRADE MARK

Look for the Red Circle Trade Mark. Accept No Other

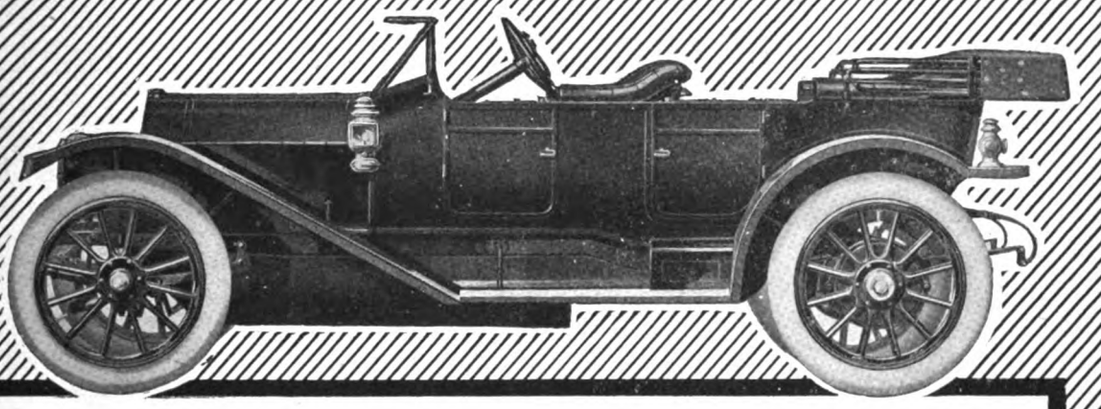
Stops Ninety Per Cent. of Tire Troubles

Stops Punctures—Stops Blow-outs

The claims made above are none too strong. If every automobile dealer and user realized the absolute truth of what we say we could not begin to supply the demand. Consider that the genuine

"Innershu" is Sold and Recommended by Over 2500 Dealers

Could there be any stronger proof? Consider that 1911 replacements amounted to less than one tenth of one per cent. of the sales. Is there any better evidence of "Innershu" efficiency? It does the work exactly as we claim. That's the whole story.



Thousands of testimonial letters from automobile owners, constantly growing sales and numerous imitations all point to "Innershu" popularity.

Dealers selling "Innershu" don't go it alone; we help them—shall we tell you how? It's worth while to find out. You can't write too soon.

American American

American Axles

Now Include the Lanchester Worm Drive as Well as the Bevel Type of Gear

The name Lanchester acquires new distinction by reason of its association with the word American.

American Axles in America stand for the same high manufacturing ideals that Lanchester implies in England.

The association of these two types creates an invincible combination, giving you the option of either form of drive, with the full assurance that each is unrivaled in its own domain.

American Axles fitted with either the bevel or worm drive, can be furnished for cars weighing up to 4,500 pounds and 60 horsepower.

Annular ball bearings are used throughout, with ample and adequate thrust bearings. Hubs may be equipped with either the annular or taper roller bearings.

One or the other of these starters will suit your every customer.

The Valentine MANIFOLD STARTER and Gas Lighter

Price $10

This manifold self starter is the equal of any manifold self starter—about the only starter that is more efficient is the Hanna Self Starter. The Gas Lighter alone is worth the price we ask for both lighter and starter.

Self HANNA Starter

Price $35

The first acetylene self starter on the market. The only 100 per cent. efficient starter that does not foul or soot your plugs. There is no other starter made that begins to compare with the Hanna. Simple, economical, works on any car.

We Want More Distributors

Our proposition to dealers is fair and liberal. There isn't a better seller on the market—and best of all our starters absolutely make good. We guarantee it and back dealers to the limit. If you're looking for a live proposition write us.

Save your knuckles by using this Jack

It's mighty disagreeable to try to lift a car with an ordinary jack and bark your knuckles. There's no such trouble with the Hartford Auto-Jack. Its long handle clears the under parts of the car and saves your knuckles.

The Hartford *saves your back*, too. It lifts a car with *one-third the effort* required by the ordinary jack. It does the hardest part of the "Strong-arm Work" so that just a movement of the wrist lifts a heavy car easily. The gears are scientifically arranged to *multiply energy*, so that slight pressure on the long lever lifts a car as if by magic.

And by a turn of the unique and convenient reversing lever down comes the car without a jerk. The action is smooth and sure both ways—*efficient*. The

Hartford Auto-Jack

is so *simple* a woman or child can operate it. Can't get out of order or get stuck. The ratchet never slips.

Maximum strength results in minimum wear. The Hartford is the strongest, sturdiest, most durable jack on the market. With a Hartford you're jack-equipped for life.

Sold by Dealers Everywhere

Almost every dealer sells the Hartford Auto-Jack. But if your dealer hasn't one in stock, we will send you one on receipt of price, with our *guarantee* to return your money at once, if you are not entirely satisfied.

The price of the Hartford, in a strong canvas containing-bag, is $8.00. A safe buy. Be sure it's a Hartford and get *superior service—now*.

FEDERAL TIRES

"Extra Service" Tires

FEDERAL TIRES are always *uniform*. You get the very *limit of mileage* out of every Federal Tire you use. This gives you a certainty in tire service—a knowledge of mileage that your tire equipment is capable of giving under all varying road conditions.

Federal Tires are tires of *unusual* quality. It is utterly impossible to use finer materials, or exercise greater skill in their construction, and as a result of this care and expense in their making they deliver the utmost in mileage service.

Automobile owners who know that quality is the secret of low up-keep expense recognize Federal Tires as the "Extra Service" tires.

Federal Tires are made in *Rugged Tread* (non-skid) and *Round Tread* types, for all rims.

Federal Tires are procurable at leading dealers. Write for interesting booklet.

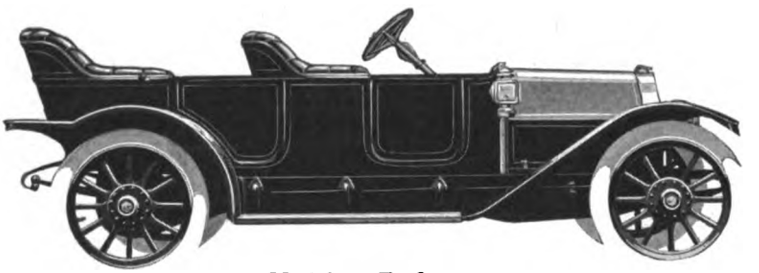
Overland

WE WANT to make it plain to you the extra value in the thirty-five horsepower Overland Model 60. It sells at $1200, but as popular priced cars go, it should be priced at $1500. This car is a bargain.



The word bargain has seldom appeared in motor car literature. It is looked on as a synonym of cut-rate.

The Overland Model 60 at $1200 is a bargain. It is more car for less money. The word fits. This Model 60 is made by the most perfect organization in the most efficient plant in the country.

This car is a product of Willys-Overland ninety-five per cent. efficiency methods; hence the bargain.

Write for Book I-44.

The Willys-Overland Company, Toledo, Ohio

Model 60-T—$1200

Wheel base, 111 inches; body, 5-passenger fore-door touring; motor, 4⅛ x 4½; horsepower, 35; Remy magneto; tires, 34 x 4 inch Q. D.; equipment, three oil lamps in black and brass finish, two gas lamps, horn and generator. Self-Starter, $20 extra.

THE MOTOR WORLD

Vol. XXXI New York, U. S. A., Thursday, April 18, 1912. No. 4

"ARMED TRUCE" IN TIRE TRADE

Diamond Meets Goodrich Prices, but United States "Stands Pat"—Bitterness Exists, but "War" Unlikely.

Because of the tense situation which existed in the tire trade during all of last week, due to the deep cut in Goodrich prices, it was expected that the present week would be marked by more or less acute developments. It was known that no little personal feeling had been aroused, and that it had given rise to threats by men in position to make them as to what might be done if certain things came to pass, or if they became ruffled to the slashing point, all of which threats proved vain because of the failure of the contingencies to arise.

On Monday, however, the Diamond Rubber Co. met the Goodrich quotations, but a day later the United States Tire Co. assumed a directly contrary attitude, and, instead of meeting the reductions, made it known that its list prices, which are approximately 16 per cent. higer than the Goodrich and Diamond figures, will be guaranteed against reduction until July 1st next. Taking, for example, the most popular size of tire, 34 x 4 inches, this means that the Goodrich and Diamond prices stand at $31.30, while the United States quotation for the same tire is $33.60. The Fisk Rubber Co., which was in the forefront of the reduction movement, also is holding fast to the $33.60 figure.

The Firestone Tire & Rubber Co. has made a reduction of about 12½ per cent. from its list prices, but as they have always ruled several dollars higher than those of the other prominent tire manufacturers, the Firestone position remains relatively unchanged.

In a sense, it may be said that an armed truce prevails, but the feeling is such, in certain quarters, that it would not take great provocation to cause renewed animation of a very vigorous sort. The action of the United States Tire Co. in guaranteeing its prices has served, however, to minimize the likelihood and to lessen the chance of a real "fight." In circular letters to the trade, the United States Co. and the B. F. Goodrich Co. have "exchanged compliments" and sought to show how each is acting for the best interests of the dealer. Each "denies the allegation and defies the allegator," so to speak, and both make fairly plain that they do not admire the attitude or arguments adopted by each other, or at any rate not as much as they admired the attitudes and arguments brought to bear in the "good old days."

To Produce Trucks in North Carolina.

J. L. Owens & Son, of Charlotte, N. C., who have been identified with the horse wagon industry for many years, have converted their business into a corporation, styled the Owens Wagon and Automobile Works, which is capitalized with $50,000. Hereafter motor wagons will be manufactured in addition to horse wagons and carriages. The officers of the new company are J. L. Owens, president; Frank O. Owens, vice-president, and Skinner S. Alston, secretary and treasurer.

Crosby Brings Suit Against Grabowsky.

Suit was instituted last week in the Wayne County Circuit Court, in Detroit, by the Crosby Co., of Buffalo, N. Y., against the Grabowsky Power Wagon Co., of Detroit, the sum involved being $1,127.32. The action is based on a promissory note dated January 2, 1912, for $564.59, given to secure payment for sheet metal stampings previously purchased, and an invoice of January 31, 1912, for the same kind of material, amounting to $562.73.

Braden Relinquishes Diamond Advertising.

Because of indifferent health, James A. Braden, for many years advertising manager for the Diamond Rubber Co. of Akron, O., has resigned that office and now is traveling in the South in an endeavor to recuperate. He has been succeeded by Clyde S. Thompson, formerly with the Fowler-Simpson advertising agency, of Cleveland.

ALLEN AGAIN BEATS THE BANKERS

Supreme Court Gives Him Judgment for Full Amount—Echo of High Finance and Allen-Kingston Car.

Judgment for $29,553.44 was given by the Supreme Court of New York on Monday last, 15th inst., in favor of the Allen-Kingston Motor Car Co. against E. R. Chapman, W. O. Allison and T. J. Lewis, formerly officers or directors, respectively, of the Consolidated National Bank of New York. The amount represents the sum of $23,500, which was sued for, plus the costs and interest, and the litigation recalls projects that looked large and carried large names, but which, subsequently, proved only expensive bubbles.

According to the exceedingly voluminous record of the case, which has been in the courts since 1908, the New York Supreme Court in 1909 gave a verdict in favor of the plaintiff for $23,500, but the Appellate Division set the verdict aside for technical reasons and ordered a new trial. This new trial took place last month, and again resulted in a victory for the automobile concern.

It appears that in July, 1907, Walter C. Allen, who substantially was the Allen-Kingston Motor Car Co., made a contract with the Kingston Motor Car Co. for 100 cars, which contract was guaranteed by those "high financiers," E. R. and O. F. Thomas, as owners of all of the Kingston company's stock. Allen paid the sum of $16,500 as a deposit to apply on the 100 cars, agreeing to pay $8,500 more at a future date, or until the sum of $250 had been paid for each car contracted for. He actually received six partly completed Allen-Kingston cars, which were exhibited at the automobile show in November, 1907, in New York. While the cars were on exhibition, Allen claims to have been told frankly by F. E. Moskovics of the Kingston company that it was then at the end of its resources and had used up all its available funds, in-

Digitized by Google

cluding the plaintiff's $16,500. Allen, of course, demanded his money back.

Negotiations were then begun with the New York Car & Truck Co., in which E. R. Chapman, president of the Hudson Trust Co., was interested. Allen was told that this company would take over the contract. He acquiesced, claiming to be ignorant of the fact that the company at that time was insolvent and unable to take over such large contracts as the one with Allen, involving $270,000. Allen alleges he soon learned he had been deceived, and sued the principals in the transaction for a return of his money. By a somewhat involved stock transaction, the Thomas brothers got rid of their interest in the Kingston company, while Allen was induced to put up the extra $8,500 and to return the six half-finished cars to be completed in the Car & Truck factory. It was claimed at the first trial that by this action he lost his claim on the Thomas brothers as well as their guarantee. He then brought suit against Chapman, Lewis and Allison, principal agents in the contract transfer, and against the Consolidated National Bank, but the trial judge dismissed the part of the action directed against the bank, permitting the action against the individual officers to be continued. When the suit again came to trial, after the verdict had been set aside by the Appellate Division, it was directed solely against the individuals named, and it is this latter suit which just has been decided.

Webbing Manufacturer to Make Tires.

E. T. Rugg & Co., who for years had been engaged in the manufacture of webbing and halters in Newark, O., has formed the Newark Auto Tire Co., which is preparing to engage in the manufacture of tires in the Ohio city. E. T. Rugg is the principal owner of the new enterprise.

Death Claims Republic Rubber Official.

L. J. Lomasney, vice-president and sales manager of the Republic Rubber Co., of Youngstown, O., whose ill health forced him to relinquish active work several months ago, died at his home in Youngstown last week. He had been so seriously ill that his death was not unexpected.

Heavy Stockholder Bids for Assets.

C. E. Latimer, of Chicago, who was the heaviest stockholder and one of the directors of the bankrupt Henry Motor Car Co., of Muskegon, Mich., has made a bid for the assets. If it is accepted, it is Latimer's intention to organize a new company and continue manufacturing the Henry car.

To Build Big Plant for Rayfield Cars.

The Rayfield Motor Car Co., which recently was organized and removed from Springfield to Chrisman, Ill., is preparing to erect a new factory in the latter town. The new structure will be 316 feet long, with a width of 20 feet at one end and 134 at the other.

BIG COMPANY TAKES UP STARTERS

Secures All Rights to Eveland Electrical Flywheel Device—Will Be Manufactured at Niagara Falls.

Following negotiations which just have been completed, the United States Light & Heating Co., which heretofore has devoted its energies to the manufacture of storage batteries and railway car electric lighting and heating systems, has acquired the manufacturing and selling rights for the Eveland electric engine starting and lighting system for automobiles, and will commence its manufacture immediately in its own shops at Niagara Falls, N. Y. Hereafter it will be styled the U. S. L. Electric Self-Starter and Lighter.

The device, which heretofore has been manufactured in a small way by Samuel S. Eveland, who controlled the patents under which is was produced and who is connected with the Philadelphia Truck Co., on whose vehicle the system has been one of the principal features, is more than ordinarily simple. It consists essentially of a combination motor and generator, the field of which replaces the flywheel as ordinarily used on automobile engines. This field is direct-connected to the crankshaft of the engine and rotates around the armature, which is anchored stationary. Thus there is no gearing of any nature, and as the speed of the generator is comparatively low, never exceeding the speed of the crankshaft, wear and tear are reduced to a minimum and there is little danger of overheating.

To crank the engine it is merely necessary to press a button, when current from a storage battery converts the generator into a motor for starting purposes. Immediately the engine starts, the motor automatically is converted into a generator and maintains the storage battery in a fully charged condition. By reason of the comparatively large size of the generator, sufficient current is available not only for side lights, head lights and tail lights, but, in the case of a commercial vehicle, also to operate electric advertising signs or novelties, and a hand searchlight for reading the addresses on packages, etc. In addition, current may also be utilized for heating purposes.

Separating Studebaker Vehicles on Coast.

The Studebaker Corporation of America is the title of a new organization which is being formed under the California laws to take over the Studebaker automobile business in that State, which at present is handled by the Studebaker Bros. Co. of California, which latter will continue to handle the Studebaker horse vehicles. Chester N. Weaver, for several years manager of the Studebaker Bros. Co., will relinquish that position on May 1st to assume the management of the new corporation. He will be succeeded by L. F. Weaver, who is at present manager of the Studebaker Bros. Co. Northwest, in Portland, Ore. As the parent Studebaker Corporation has in process of development a full line of motor trucks and delivery wagons, the new California company will be able to present a complete line of motor vehicles of all types

Victor Attracts New Men and Money.

As the result of the internal reorganization which is now in progress, it is extremely probable that very much more will be heard of the Victor truck and the Victor Motor Truck Co., of Buffalo, N. Y. New men and new capital have been interested, among the men being Orson E. Yeager, a wealthy lumberman, who also is the head of the Buffalo Chamber of Commerce and who has become president of the Victor company. Other changes are pending, but Olin L. Neal remains with the company as vice-president, and James G. Budd, formerly with the Alden Sampson organization, will continue as general manager, which post he has filled for the past year.

A new and broader policy will be adopted and in general things will be made to hum. While more attention than ever will be paid to the production of trucks, special efforts will be made in the development of fire department apparatus.

Elmore Establishes Three Branches.

Having taken over the territory which previously was handled on an agency basis, the Elmore Mfg. Co., of Clyde, O., has established factory branches in San Francisco, Los Angeles and Fresno, Cal. R. A. Wood has been appointed manager for the Los Angeles branch and C. W. Hobson manager for the Fresno branch, but A. J. Smith, who will be located at the San Francisco establishment, will have general direction of the Elmore business on the Coast.

Everitt Car Enters Great Britain.

The Everitt car is the latest American production to obtain a foothold in Great Britain. It will be handled by the Everitt-Gascoine Co., at 89 Wigmore street, London, the moving spirit in this company being M. Gascoine, who for many years was the London representative for Armstrong-Whitworth, Ltd.

American Motors Plant to be Enlarged.

The American Motors Co., of Indianapolis, has let contracts for the erection of a three-story brick and concrete addition to its present plant in that city. It will represent a cost of $12,000.

United Rim No. 5 Sees the Light.

The United Rim Co., of Akron, O., has brought out a new rim which already is being shown to the trade. It will be known as United Rim No. 5.

MILLIONAIRES IN ELECTRIC TRUCKS

Seven of Them Back a New Company Which Arises, Ready for Business—Factory Located in New Jersey.

Without fuss or fireworks, but with the backing of seven men who are described as multi-millionaires, but whose identities have not been disclosed, the Atlantic Vehicle Co., which recently was incorporated under the laws of New Jersey with $390,000 capital stock, had its plans so well laid that it already is in possession of a temporary factory in Newark, N. J., and a commodious general office at 1600 Broadway, New York, with the electric truck which it will manufacture practically ready for production.

The active men in the project are McKinley Boyle, president and treasurer of the company; Ralph Sanger, who is vice-president and sales manager, and M. Black, who is secretary. Arthur J. Slade, one of the most experienced and best known truck designers and engineers in this part of the country, is chief engineer of the Atlantic company, and the trucks which will be produced are of his design. They will comprise vehicles of 1, 2, 3½ and 5-ton capacity, and will sell at from $2,400 to $4,000. The first one has been in actual operation for several months and has given a good account of itself.

The factory at Newark, which ultimately will give way to a larger structure, is located at Oraton street and Verona avenue.

The Atlantic trucks will employ two brand-new motors recently developed by the General Electric Co., which are said to be distinct improvements on anything of the sort available.

McKinley Boyle, the president and treasurer of the new company, is president also of the Continental Car Co., of Lousiville, Ky. Ralph Sanger, the vice-president, was a member of the well-known machinery firm of Wanham, Sanger & Bates.

Grant "Six" Fathered by Grant-Lees.

It finally has been made known that the Grant Motor Car Co., of Cleveland, O., which recently was formed to manufacture the Grant "six," is a direct offshoot of the Grant-Lees Machine Co., of that city, and that it will occupy the immense concrete factory, 100 x 100 feet, which the Grant-Lees people now have in course of erection.

As the Motor World stated three weeks since, H. H. Elmer, former general manager of the Haynes Automobile Co., of Kokomo, Ind., and later one of the organizers of the abandoned Elmer Auto Corporation, of Elkhart, Ind., is president of the Grant Motor Car Co., but it transpires that he has become also vice-president and general manager of the Grant-Lees Machine Co. itself.

The Grant "six" is design of Charles E. Lohr, one of Elmer's colleagues in the Haynes organization, who has become chief engineer of the Grant Motor Car Co. It will be made in one chassis only, and will list at $2,750, fully equipped. Deliveries will commence about the last of the present month.

In addition to Lohr, H. H. Murden, James L. Worthington and E. L. Lawrence, all of whom previously were identified with Elmer, and who are engineers of ability, are associated with him in the Grant enterprise, as previously was stated by the Motor World.

Collapsing Roof Damages New Cole Plant.

Due to the collapse, on Monday last, of a concrete roof of the Cole Motor Car Co.'s new plant in Indianapolis, a carpenter at work on the premises was killed and a money loss of about $5,000 sustained. The building is a four-story structure, of which only the first floor had been completed and occupied. It had not yet been turned over to the Cole company. Work on the building was started last fall, but shortly after the collapse of the Prest-O-Lite company's new plant in October, the Indianapolis authorities ordered all concrete work stopped, and labor on the Cole building ceased. It is believed that the unfinished roof, which was made of cinders, tar and contrete, and which had been left unprotected by tar paper, had become frozen and that consequence of warm weather rendered it unsafe.

Wilkinson Motor Starter Fairly Started.

The Wilkinson Motor Starter Co., which has been in process of formation in Detroit for some time, has completed its organization by the election of Fred Stevenson, president, Benson E. Brown, vice-president and general manager, and R. W. Wagar, secretary and treasurer. The company is capitalized with $50,000, and will market a mechanical starter made under the Wilkinson patents, which are fairly well known in Detroit. It starts the motor by revolving the flywheel, the necessary impetus being given by pressure on a dash pedal. It is so well thought of that it is said three Michigan car manufacturers are having it especially attached to their cars, with a view of adopting it as standard equipment for 1913.

Continental Truck Succeeds Barnsdale.

The Continental Truck Mfg. Co., which succeeded to the business of the Barnsdale Auto Co., of Superior, Wis., has been incorporated with $50,000 capital stock. E. M. Anderson is president and J. G. Barnsdale secretary and treasurer. The 1-ton and 3-ton trucks which the company will produce will be styled Continentals.

London House Takes on American Truck.

While American cars have made great progress in England, American trucks have not kept pace with them, only a comparative few of the better-known brands being in use on the other side. The Schacht motor wagon, however, has just been taken up by the Schneider Motor Co., of London.

OFFICERS RAISED THEIR SALARIES

But Minority Stockholders of Horseless Age Charge It was Illegal and Bring Suit—Old Friends Fall Out.

Samuel B. Stevens, "suing on behalf of himself and on behalf of all of the stockholders of the Horseless Age Co. similarly situated, who may come in and share the expenses of his action," to quote the legal phraseology, has instituted an action in the New York Supreme Court against the Horseless Age Co., Frederick J. Wagner and Charles B. Ames, which in effect is designed to force Wagner and Ames to show legal authority for their action in increasing their respective salaries, as president and vice-president, from $100 per week to $1,000 per month, and to compel them to return to the company all sums in excess of $100 per week which they paid to themselves since October 1, 1910.

While he is not named as a defendant in the action, T. B. Van Alstyne, to whom Wagner, "at the request of Ames," sold a portion of his stock in November last, is more or less directly a party to the litigation. Wagner, who at the time the alleged illegal action was taken, was president of the Horseless Age Co., retired about the first of the year, having sold the remaining portion of his stock to Ames, who then became president and treasurer, Van Alstyne succeeding Ames as vice-president. According to the complaint, the new officials lost no time in "getting busy." Being in control of the company, after electing themselves to their respective offices, they fixed Ames's salary at $12,000 per year and Van Alstyne's at $18,000.

Ames and Wagner are charged with "conspiring together at the expense of the company and its stockholders," and of "diverting and appropriating the company's assets without any right, warrant or authority," and of "fraudulently and wilfully violating their duties as directors of the company."

The special meeting at which they "appropriated to themselves, under the guise or pretense of salary, the sum of $1,000 per month each," is claimed to be illegal in that Stevens, as the third director, was not notified that such a meeting was to be held or was contemplated, and also because their action had not been ratified by either the directors or other stockholders of the company.

It is charged that at none of the meetings held subsequent to their action did Wagner or Ames say anything about having boosted their salaries. At the annual meeting in December last, when Van Alstyne and Ames, who controlled 52 per cent. of the stock, elected themselves to office and voted themselves salaries of $12,000 and $18,000 per year respectively, and despite the objection and protest of

Digitized by Google

holders of the remaining 48 per cent. of the stock, Wagner, Ames and Van Alstyne, "acting together, attempted to confirm the aforesaid misappropriation of corporate assets."

Demands for the return of the money having failed of effect, and Van Alstyne and Ames "being in absolute control and hostile to the plaintiffs," Stevens alleges that he had no adequate remedy at law, and therefore asks the court to direct the defendants to return to the corporation "all moneys unlawfully, improperly and fraudulently taken," and for such other relief as the court may deem just and proper.

While the legal phraseology makes it appear that Stevens is alone in instituting the action, it is well known that three other men, prominently identified with the New York automobile trade, who also are stockholders in the Horseless Age Co., are acting with him. Indeed, it is stated that Stevens and his three colleagues furnished practically all of the money when the Horseless Age was purchased in 1909 from its original owner, and that in a spirit of friendship and out of goodness of heart they conveyed to Wagner and Ames the controlling interest. Quite apart from the money involved, they feel that they have been badly treated by those in whom they entrusted such faith, and consider that friendship and goodfellowship have been strained to the breaking point.

Beitler Wants Money Back and Expenses.

Alleging a breach of contract and professing general dissatisfaction with two trucks furnished him for "demonstrating purposes," Jesse J. Beitler has brought suit in the New York Supreme Court against the W. H. McIntyre Co., of Auburn, Ind., for $2,098.49—which sum is said to represent the amounts he paid for the trucks and his own expenses for rent, advertising, etc., while acting as an agent for the McIntyre cars several years ago.

According to the complaint—which in its references to the Selden patent and "licensed" cars, etc., reads like a saga from a long-forgotten past—Jesse J. Beitler was doing a somewhat unprofitable business in New York City under the style Import-Export Motor Co., with headquarters at 1777 Broadway. His contract with the McIntyre company, it is explained, contained the provision that all cars furnished to him for sale in New York were to carry his own name plate, or rather that of the Import-Export company, and that Beitler was not to handle any cars not licensed under patent No. 549,160 (the Selden patent). After Beitler had received two light trucks, paying therefor $1,348 in cash, he claims he found them unsatisfactory, and could not sell them. In addition to the return of the purchase money he believes he is entitled to a refund of all the money spent for rent and office expenses and advertising, and therefore sues for $1,348 plus $751.49, or a total of $2,098.49, besides the usual interest and costs.

HOW GOODYEAR MELON WILL BE CUT

While 100 Per Cent. Stock Dividend Will Be Declared, Not All New Issue Will Be Sold—The Plan.

Further details of the 100 per cent. "melon" which will be cut by the Goodyear Tire & Rubber Co., of Akron, O., in consequence of its increase of capital from $6,000,000 to $15,000,000, which was briefly reported in last week's Motor World, discloses that of the new capital, $10,000,000 will be common and $5,000,000 preferred stock. Only $5,000,000 of the common and $2,000,000 of the preferred will be issued immediately, however, leaving $5,000,000 of the former and $3,000,000 of the latter in the treasury. Of the present capitalization, $2,284,100 of the $2,500,000 common stock is outstanding, and of the $3,500,000 preferred but $1,000,000 is outstanding.

Present holders of the common shares will receive a 100 per cent. common stock dividend and the right to subscribe for $341,800 of new common at par. The old preferred is to be retired at 105, and holders have the right to subscribe for the new preferred share for share at par, after which rights to the new preferred revert to the common stock. The new prferred is 7 per cent. cumulative and is retirable after 1915 at 120. It is not known what rate of dividend the new common will pay, but shareholders anticipate that the present 12 per cent. rate will prevail.

The $5,000,000 common and the $3,000,000 preferred held in the treasury indicate possibilities of other melons in the meantime if conditions justify, the preferred being ample to take care of the further growth of the company.

Goodrich Denies Long Island Purchase.

Published reports that the B. F. Goodrich Co. had purchased a large building site on Jackson and Honeywell avenues, Long Island City, New York, are emphatically denied at the New York office of the Goodrich company. The recent action of the Goodrich company in exchanging its Ohio charter for New York incorporation had given rise to rumors that a factory would be built in New York State, thereby giving apparent color to the reported Long Island City transaction, but Manager Yule, of the Goodrich branch, states that the first the Goodrich people knew of the matter was when it appeared in print.

Nova Scotians Form $2,000,000 Company.

After a more or less extended period of negotiation, the Nova Scotia Carriage Co., of Kentville, N. S., has been taken over by the Nova Scotia Carriage & Motor Car Co., of Amherst, N. S., which was organized for the purpose. The new concern has been incorporated with a capital of $2,000,000, consisting of $750,000 preferred stock, $1,250,000 common stock and an authorized bond issue of $250,000. The bonds and a portion of the stock, totaling $600,000, will be issued to meet present needs and will be expended chiefly in the erection and equipment of a new plant in Amherst, which it is expected will be completed early this fall. The directors of the new company are: M. G. Winters, St. Johns, Newfoundland; N. Curry, Montreal; Hector McInnes; Percy C. Black, president of the Amherst Boot & Shoe Co.; H. W. Wentzell, Halifax; W. B. Tennant, J. W. Regan, Halifax; A. J. Price, Quebec. D. W. McKay, of the Kentville concern, will be the managing director, and his brother, D. C. McKay, will have charge of the sales department.

Wilson Becomes Kelly-Racine's President.

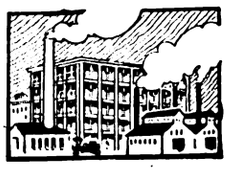
George E. Wilson, former purchasing agent for the Mitchell-Lewis Motor Co., of Racine, Wis., has been elected president and general manager of the Kelly-Racine Rubber Co., of that city, in which the Mitchell-Lewis interests are largely interested. Wilson succeeds Charles F. U. Kelly, who, however, retains close identification with the company which he was instrumental in organizing; he has been made vice-president and henceforth will devote more attention to the sales management than to the more purely executive affairs. Stewart Webster is secretary and treasurer of the company. In addition to these officers, W. M. Lewis and Martin J. Gillen comprise the board of directors.

Clark Causes Excitement in Montpelier.

J. B. Clark, who recently organized the Shelbyville Motor Car Co., in the Indiana town of that name, is seeking to obtain a factory in the nearby town of Montpelier in that State. Clark claims to have more orders in hand than he is able to fill, but he desires the Montpelier folk to subscribe for $10,000 worth of his company's stock, and to provide a factory building free of rent for a prescribed period. Montpelier became sufficiently excited over the prospect to call a meeting of its leading citizens in the city hall, at which the proposal was discussed and a committee appointed to solicit the necessary subscriptions.

More Room for Willard Storage Batteries.

Due to the necessity for more "elbow room," the executive offices of the Willard Storage Battery Co., of Cleveland, O., have been moved to 5760 Euclid avenue. In addition, the Willard company has broken ground for a factory extension, which will add approximately 25,000 square feet to its present facilities.



Increases Shown by Franklin Records.

According to the records of the Franklin Automobile Co. of Syracuse, N. Y., the sales of its branch houses already are 144 per cent. in excess of the sales at this time last year. The sales of Franklin dealers for the corresponding period show an improvement of from 100 to 300 per cent.

THE WEEK'S INCORPORATIONS

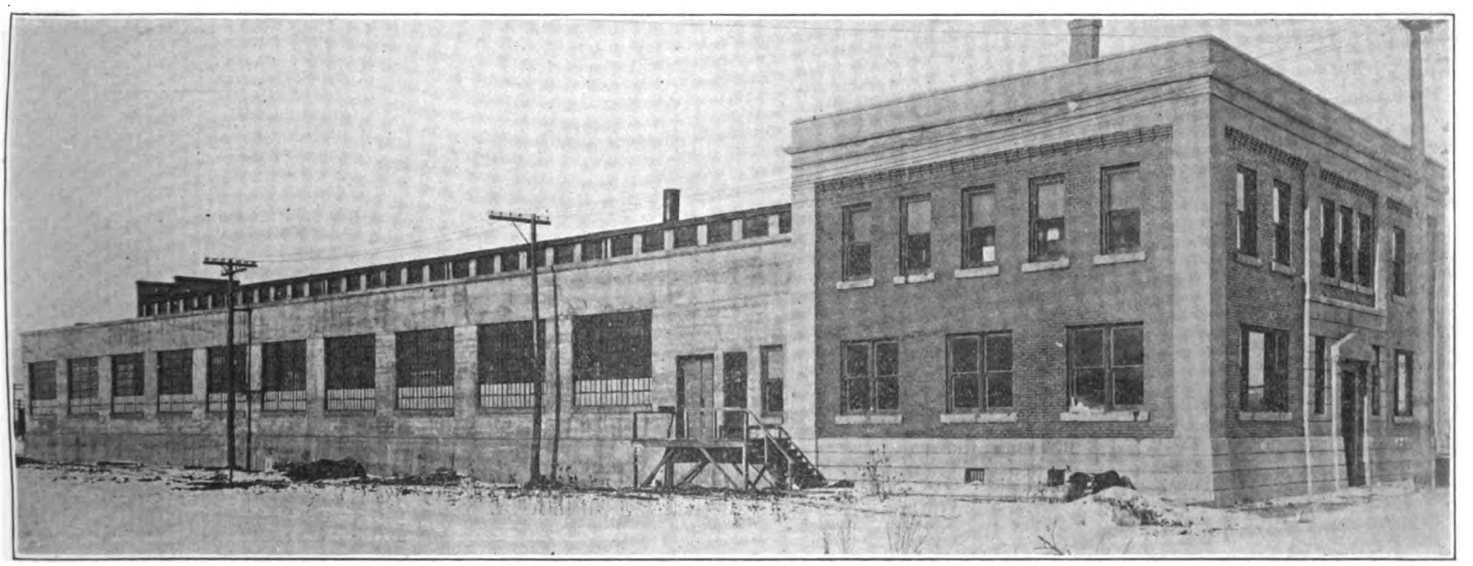
Detroit, Mich.—Suburban Motor Car Co., under Michigan laws, with $500,000 capital; to manufacture motor cars.

Chicago, Ill.—Chicago Automobile Trade Association, under Illinois laws. Corporators—N. H. Van Sicklen, Harry N. Fowler, Henry Paulman.

Columbus, O.—Middletown Motor Car Co., under Ohio laws, with $15,000 capital; to deal in motor cars. Corporators—D. N. Gingerick and others.

New Orleans, La.—Cadillac Motor Co., under Louisiana laws, with $20,000 capital; to deal in motor cars. Corporators—C. W. Harrington and others.

Baltimore, Md.—Charter Automobile Co., under Delaware laws, with $75,000 capital; to deal in automobiles. Corporators—C. R. Fouts, W. E. Byrd, G. H. Reinhardt, Baltimore.



Grand Forks, N. D.—Lyons Auto Co., under North Dakota laws, with $15,000 capital; to deal in motor cars. Corporators—J. W. Lyons, M. J. Lyons, M. M. Jones.

Pasadena, Cal.—Crown City Garage Co., under California laws, with $25,000 capital; to operate a public garage. Corporators—James G. Dickey, Charles L. Wood, Henry Taylor.

Hastings, N. Y.—Post Road Transportation Co., under New York laws, with $100,000 capital; to operate motor busses for hire. Corporators—George T. Brown, Cyrus F. Judson, Paul Hayes.

Milwaukee, Wis.—Sigmund Auto Truck Co., under Wisconsin laws, with $50,000 capital; to manufacture motor trucks. Corporators—Frederick F. Giese, Albert Brandenberg, Robert N. Sessions.

Yonkers, N. Y.—Hudson River Automobile Co., under New York laws, with $500 capital; to deal in motor cars. Corporators—Charles Wieland, Richard Jeggle and Carl Schmeid, all of Yonkers.

WHERE THE BRIGGS-DETROITER CO. PRODUCES DETROITER CARS IN DETROIT

Chicago, Ill.—Pilot Automobile Co., under Illinois laws, with $5,400 capital; to deal in motor cars. Corporators—W. A. Dugane, C. H. Rodenbach, A. E. Pattison.

Victoria, Tex.—Victoria Motor Car Co., under Texas laws, with $5,000 capital; to deal in motor cars. Corporators—Welder Daniel, J. T. Linebaugh, W. H. Craine.

Biddeford, Me.—Etchelle Auto Co., under Maine laws, with $10,000 capital; to deal in motor cars. Corporators—Joseph Etchelle, Charles V. Tanner, Arthur L. Roberts.

Cleveland, O.—B. N. C. Motor Truck Co., under Ohio laws, with $5,000 capital; to deal in motor trucks. Corporators—R. A. Wilbur, A. S. Dole, H. H. Coyne and others.

Yonkers, N. Y.—Yonkers Auto Service Co., under New York laws, with $2,000 capital; to operate a garage. Corporators—George Fry, Edward Keale, F. P. Hoffman.

Chicago, Ill.—Star Motor Delivery Co., under Illinois laws, with $75,000 capital; to do a general delivery business. Corporators—James E. Hauronic, F. R. Buri, Frank P. Paige.

Milwaukee, Wis.—Wisconsin Retail Automobile Dealers' Association, under Wisconsin laws. Corporators—Nathan Haessley, T. J. Edwards, L. F. Schoelkopf and U. C. Moore.

East Aurora, N. Y.—East Aurora Motor Car Co., under New York laws, with $8,000 capital; to deal in motor cars. Corporators—Arthur L. Pierce, Manley B. Paxon, Winfield S. Wilson.

Jennings, La.—Jennings Garage & Machine Shop, under Louisiana laws, with $25,000 capital; to operate a garage and repair shop. Corporators—S. J. Johnson, S. K. Johnson and others.

Chicago, Ill.—Illinois Motor Patents Corporation, under Illinois laws, with $5,000 capital; to manufacture motor cars and parts. Corporators—William D. Kirk, Edward C. Marsh, George E. Daniels.

Buffalo, N. Y.—Eadie Vehicle & Gear Co., under New York laws, with $200,000 capital; to manufacture motor cars and parts. Corporators—John M. Eadie, George P. Keating, Seward H. Millener, all of Buffalo.

Utica, N. Y.—Bauer-Jackson Auto Co., under New York laws, with $2,000 capital; to deal in motor cars. Corporators—Walter C. Bauer, 31 Oneida street; Foster G. Jackson, George H. Jackson, both of 14 Maple street.

New Rochelle, N. Y.—Cedar Auto and Marine Co., under New York laws, with $2,500 capital; to operate a garage and machine shop. Corporators — Fernell D.

Digitized by Google

Franckling, Charles A. McGill, Albert B. McGill.

Dover, Del.—Motor Vehicle Speed Alarm Co., under Delaware laws, with $500,000 capital; to manufacture automobile accessories. Corporators—H. O. Coughlan, J. F. Curtain, New York City; J. M. Saterfield, Dover.

New York, N. Y.—Royal Motor Truck Co. of New York, under New York laws, with $10,000 capital; to deal in motor trucks. Corporators—Arthur J. Cohen, William S. Weiss, Harry J. Leffert, all of 45 Wall street.

New York, N. Y.—E. D. Gear Co., under New York laws, with $60,000 capital; to manufacture gears, etc. Corporators—Daniel J. Rice, 149 West 35th street; James P. Eadie, 141 Ninth avenue; George Keating, 287 Broadway.

Cleveland, Ohio—D. H. Hutchcroft & Sons Co., under Ohio laws, with $10,000 capital; to deal in automobiles. Corporators—D. H. Hutchcroft, Glidden W. Hutchcroft, Thornton Hutchcroft, William Merts and S. H. Meacham.

New York, N. Y.—Elsmere Cab & Car Co., under New York laws, with $1,000 capital; to conduct an automobile livery business. Corporators—Eleanor Engledrum, Mary E. Morgan and John Engledrum, all of 789 Elsmere place.

Middletown, Conn.—Tucker Garage Co., under Connecticut laws, with $50,000 capital; to operate a public garage and deal in automobiles. Corporators—Willard D. Tucker, G. Howard Tuttle, Clare H. Blatchley, all of Middletown.

Albany, N. Y.—Kingsbury-Leahy Co., under New York laws, with $40,000 capital; to manufacture vehicles. Corporators—Edward W. Leahy, 9 LaFayette street; Jacob S. Kingsbury and Sarah M. Kingsbury, both of 4 Jay street.

New York, N. Y.—National Tire Co., under New York laws, with $50,000 capital; to deal in automobile tires. Corporators—Harry Davies, 246 West 46th street; Thos. H. Hopkirk, 30 Church street; Ivan W. Weisbrod, St. George, S. I.

New York, N. Y.—Sullivan Garage Co., under New York laws, with $15,000 capital; to operate a public garage. Corporators—M. E. MacAdam, 92 Morningside avenue; John N. MacAdam and Peter B. Riley, both of 121 West 42d street.

Little Rock, Ark.—Puncture-Proof Tire & Wheel Co., under Arkansas laws, with $25,000 capital; to manufacture automobile tires and wheels. Corporators—R. B. Sutton, F. L. White, R. W. Griffith, O. D. Longstreth and John Farmer.

Wilmington, Del.—Non-Skid Chain Co., under Delaware laws, with $250,000 capital; to manufacture anti-skid devices. Corporators—A. C. Platt, E. Van Etten, Edward E. Johnstone, W. J. Arkell, New York City; H. W. Davis, Wilmington.

Parkersburg, W. Va.—Logan Carriage & Automobile Co., under West Virginia laws, with $25,000 capital; to build carriages and automobiles. Corporators—Henry Logan, Thomas Paige, Henry Huffman, Herman Dills, B. F. Stout, all of Parkersburg.

Brooklyn, N. Y.—D. S. P. Automobile Specialty Co., under New York laws, with $5,000 capital; to deal in automobile specialties. Corporators—Chas. F. Sendall, 63 Kingston avenue; William Price, 286 Fulton street; George Sendall, 957 57th street.

Brooklyn, N. Y.—Eureka Non-Skid Manufacturing Co., under New York laws, with $2,500 capital; to manufacture anti-skid devices. Corporators—Henry E. Bradford, East Williston; James Colburn, London, England; Brown Holston, Plainfield, N. J.

New York, N. Y.—Amsterdam Starter Co., under New York laws, with $5,000 capital; to manufacture engine starters. Corporators—Edwin S. Greene, 19 Manhattan avenue; Rufus L. Weaver, 115 Broadway; Sarah S. Weaver, 651 West 179th street.

New York, N. Y.—Eclipse Rubber & Tire Co., under New York laws, with $50,000 capital; to deal in tires, etc. Corporators—Simon J. Schwartz, 347 Fifth avenue; Arthur A. Glass, 301 West 108th street; Harry A. Bloomberg, 5 Beekman street.

New York, N. Y.—Combination Transmission Clutch Co., under New York laws, with $10,000 capital; to manufacture an automobile transmission system. Corporators—Louis Romeisler and George Isaken, of 135 Broadway, and Herman Gustow, 235 Broadway.

Yonkers, N. Y.—Yonkers Auto Service Co., Inc., under New York laws, with $2,000 capital; to manufacture automobiles. Corporators—George G. Frey, Mamaroneck; Frank P. Hoffman, 25 Broad street, New York City; Edward Keale, 202 Patchen avenue, Brooklyn.

New York, N. Y.—Eighteenth Street Garage Co., under New York laws, with $5,000 capital; to operate a public garage. Corporators—William F. Donnelly, 407 W. 22nd street; Daniel E. Peel, 360 W. 21st street; Abraham E. Magnus, 836 Jefferson avenue, Brooklyn.

New York, N. Y.—R. A. S. Spring and Bumper Co., Inc., under New York laws, with $1,000 capital; to manufacture automobile accessories. Corporators—George Steller, 56 Gold street; Victor H. Anderson, 251 Fourth avenue; George Pinkenberger, 12 East 42d street.

New York, N. Y.—Auto Truck Storage & Exchange Co., under New York laws, with $20,000 capital; to operate a garage and exchange business. Corporators—Henry J. Benjamin, 55 West 73d street; Louis H. Moos, 501 West 110th street; Leopold O. Rothschield, 251 West 138th street.

New York, N. Y.—Mitchell-Edmonston Garage, Inc., under New York laws, with $10,000 capital; to operate a public garage. Corporators—Leland A. Mitchell, 9 Fort Washington avenue; George W. Edmonston, 460 Bloomfield avenue; Joseph P. Bickerton, Jr., 104 West 70th street.

Changes Among Prominent Tradesmen.

John W. Bate, for many years superintendent of the Mitchell-Lewis Motor Co., of Racine, Wis., has resigned that office. He, however, remains a director of the company.

W. H. Hunt, former manager of the San Francisco branch of the Goodyear Tire & Rubber Co., has joined the Franklin Automobile Co. in that city; he will be attached to the sales department.

W. G. Johnson has been appointed chief engineer for the Garford Co., of Elyria, O. He succeeds C. A. Neracher, who resigned to join the engineering staff of the Willys-Overland Co., of Toledo.

A. J. Rogers, heretofore identified with the sales department of the Remy Electric Co., of Anderson, Ind., has been transferred to the management of the Remy branch in San Francisco. He will have general direction of the Remy business on the Pacific Coast.

E. F. Lake has been appointed laboratory manager for the Perfection Spring Co., of Cleveland, O. Lake at one time was one of the editors of the American Machinist, but more recently has been conducting a consulting metallurgical business on his own account.

T. A. Peck has been appointed manager of the Metzger Motor Car Co.'s technical department in Detroit. Although he received his training in the Brown & Sharpe works, in Providence, R. I., Peck has been connected with the mechanical end of the automobile industry almost since its inception.

R. S. Bryant has been appointed consulting engineer of the Standard Welding Co., of Cleveland, O. He previously was identified with the Bryant Rim Co., of Columbus, O., in a capacity which carries with it the knowledge and experience necessary to measure up to the Standard Welding's high standard.

The office and salesroom of the American Locomotive Co., at 1886 Broadway, New York, having been designated an Alco branch, A. D. Frost has been appointed its manager. He previously was connected with the establishment as manager of local sales. In his new capacity, Frost will have charge also of the Alco service building in Long Island City.

William McGlashan, for many years designing engineer for the Winton Motor Carriage Co., of Cleveland, O., has resigned to become chief engineer for the Studebaker Corporation at the latter's South Bend (Ind.) factory. As heretofore, practically all of the Studebaker automobile work has been performed at the Detroit factory. McGlashan's appointment to the post of chief engineer may or may not be significant.

Knute Knudson has opened a garage in Delhi, Minn.

Wind Bros. have opened a garage in New London, Iowa.

I. C. Devis and W. T. Stolt are building a garage in Corsica, S. D.

Naegeli Brothers are building a garage and repair shop in Fairdale, N. D.

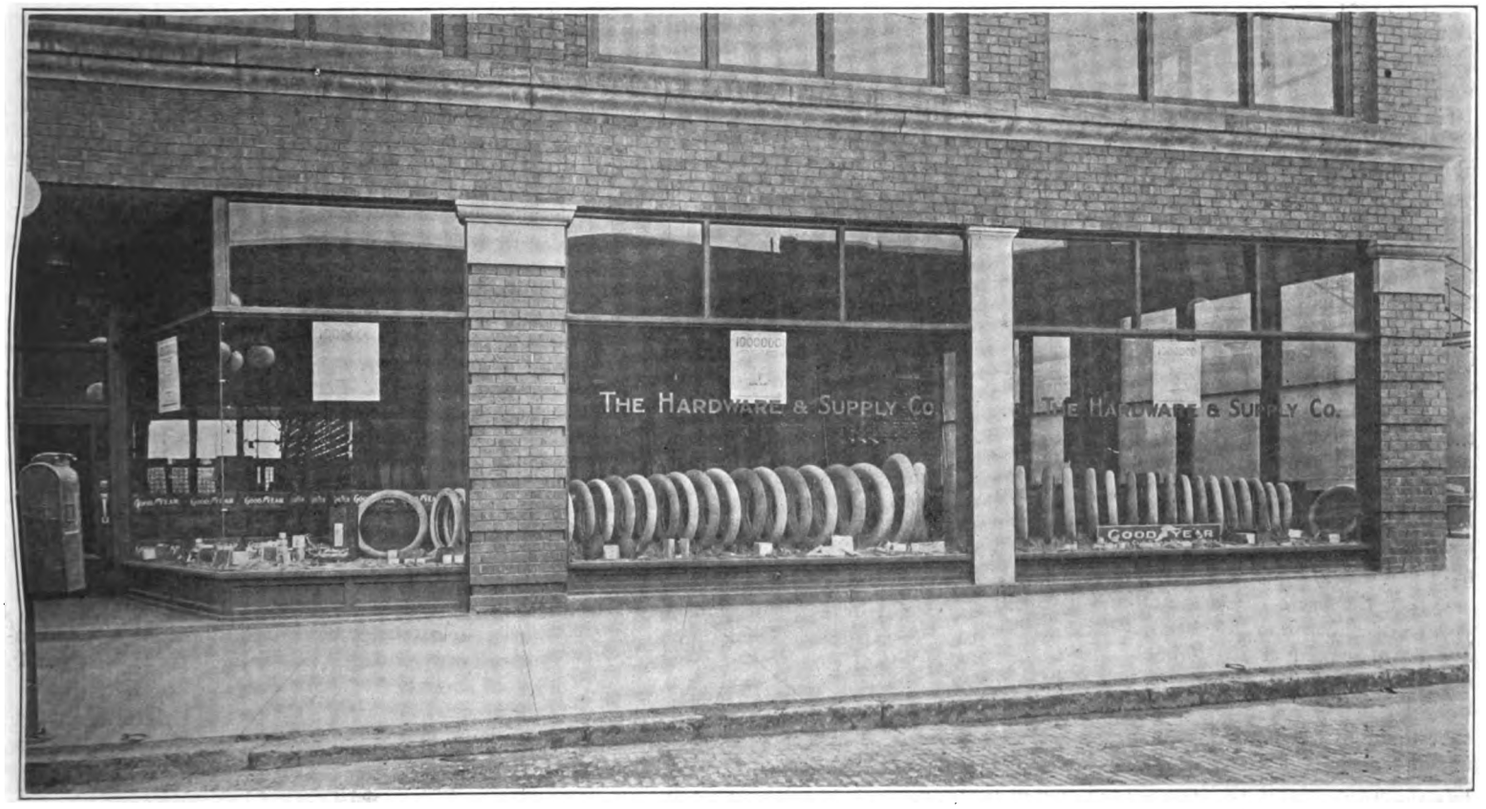
Chelsea, Mich., will soon have a modern garage. L. G. Palmer is building it.

J. C. Hanford is preparing to open a garage in Colfax, Wash. He has the agency for Cadillac cars.

Louis Medalen, of Lake Johanna, Minn., is preparing to open a garage in Belgrade, in the same State.

William Ness and Albert Johnson have formed a partnership and opened a garage in Zumbrota, Minn.

At a cost of $14,000, a cement garage is



a salesroom in Burlington, Iowa, where they will handle the Michigan car.

John Grandy and Cliff O'Hara have rented the Craig building, in Bathgate, N. D., and opened a garage and repair shop therein.

Malcolm P. Burbank has opened a garage and salesroom at 805 Main street, Worcester, Mass., where he will show Pullman cars.

The Lake Shore Tire Co., of Sheboygan,

EVIDENCE THAT TIRES CAN BE DISPLAYED TO ADVANTAGE IN A SHOW WINDOW

The display in an Akron show window is made up of 43 Goodyear tires of both the non-skid and the plain tread type, ranging in size from 44 x 5½ to 28 x 3. The arrangement of the tires, laid on a bed of sea green muslin, is a reproduction of a recent advertisement of the Goodyear Tire and Rubber Co. entitled "The Floodlike Advance."

Charles Bryant and A. S. Stapleton are building a garage in Virginia, Mont.

J. H. Zander and Herman Krueger are building a garage in Browntown, Minn.

W. W. Savage has engaged in the automobile repair business in Janesville, Minn.

G. E. Loeffelbein is preparing to open an automobile livery and garage in Martin, N. D.

F. T. Bolton has opened a repair shop and garage at 125 Sixteenth street, Portland, Ore.

At a cost of $12,000, Samuel Foster is building a garage at 720 Barr street, Fort Wayne, Ind.

being built in Mulvane, Kans. It will be occupied by Bert Snively.

S. L. Pemberton is making ready to build a garage at the corner of Oak and Nebraska avenue, Tampa, Fla.

M. P. Carpenter has formed a partnership with A. Rossi and is building a garage and machine shop in Divon, Cal.

Will Evans has purchased the Sedalia Auto Garage, in Sedalia, Mo., from W. H. Highleyman, the former owner.

The Economy Auto Co., agent for Cole cars in Oskaloosa, Iowa, has changed its name to W. M. Novak Auto Co.

Dr. Madison and H. Cameron have opened

Wis., has changed hands. A. M. Schuerle, the former owner, has sold out to Joseph Arle.

Walter B. Sheldon believes that Red Wing, Minn., needs a modern garage, and is building one on Main street to supply the deficiency.

E. W. Hill has taken over the agency business of the White Motor Car Co., of Portland, Ore. He will handle White cars in the whole State.

William Cappis has sold a half interest in his garage at Blair, Neb., to Louis Latta. The new firm will do business under the style Blair Auto Co.

Digitized by Google

An electric garage, salesroom and service station for Lansden electric trucks has been opened in Chicago at 1000 Michigan avenue. C. P. Jaeger is manager.

Henry Putnam has purchased the livery business of Holger Mortisen in Penfield, Ill. He will add automobiles to the business and conduct a garage.

C. L. Landis, formerly with the Esterline Co., Lafayette, Ind., has purchased a half interest in the Fashion Garage & Automobile Co., in Indianapolis.

W. D. Saywer and G. C. Whitemore have formed the Taxicab Service Corporation in Portland, Me. A garage is being erected for them on Spring street.

The Stevens-Duryea Co., of Chicopee Falls, has established a retail branch in Hartford, Conn. It will be under the management of M. H. Parsons.

J. J. Hayes, in Chisholm, Minn., has commenced business in temporary quarters pending the completion of a garage for which plans have been drawn.

F. D. Davis has opened an automobile salesroom at 772 West Walnut street, Springfield, Mo. He will handle the Metz runabout in the Ozark country.

The Vesta Motor Car Co. has opened a service building on Baum street, Pittsburgh, Pa., where it will care for the needs of Stevens-Duryea and Velie owners.

J. E. Chapman and Robert H. Love have formed the Chapman-Love Motor Car Co. and opened a salesroom at 1509 Fourteenth street, Washington, D. C. They will handle the King car.

The North Garey Garage, in Pomona, Cal., has been sold to F. C. Howland, of Pasadena. The sale carries with it the agency for Studebaker, E-F-M and Flanders cars.

Under the style of Automobile Clearing House, a salesroom for second-hand cars has been opened at 20 Wabash street, Indianapolis, Ind. E. J. Kane is the head of the enterprise.

William S. Lewis, of Eastman, Ga., trading under the style of Eastman Garage Co., has filed a voluntary petition in bankruptcy. He places his assets at $893.51 and his liabilities at $2,222.70.

Henry Luhrmann has purchased the real estate and agency contracts of the Imperial Motor Car Co., on Walnut Hills, Cincinnati, Ohio. The Imperial company has a capitalization of $150,000.

W. A. Griffing, who formerly handled motorcycles in Spokane, Wash., has gone into the automobile business and opened a garage in Missoula, Mont. He has the agency for Metz runabouts.

The Central Motor Sales Co. is the style of a new concern which just has "opened up" at 815 Sycamore street, Cincinnati, O., with T. A. Perkins as manager. Brush cars are to be handled exclusively.

The Automobile Owners' Supply Co., of Washington, D. C., is now on the way to become a mere memory. The receivers have been authorized to sell the assets of the company to the best advantage.

The Taylor Motor Car Co. has been formed by John Taylor, in Pittsburgh, Pa., to distribute Lippard-Stewart commercial cars in Western Pennsylvania. Its headquarters are at 7125 Kelley street.

E. H. Lambert, for many years connected with the Franklin agency in San Francisco, Cal., has gone into business on his own account and opened a garage and repair shop at 1420 21st street, Sacramento.

Clyde F. Sandt, of Martin's Creek, Pa., has opened salesrooms at the Imperial Garage, 51 North Sitgreaves street, Easton, Pa. He has the agency for the Overland, Maxwell, Columbia, Brush and Metz cars.

The Marietta Motor Co., of the Ohio city of that name, has purchased the Al Anderson Garage in the same city. The consolidated business will be located at the old Anderson garage, on Front street.

The Viehman Auto Co. has been organized in Minneapolis, Minn., for the distribution of Auburn cars in Minnesota, Wisconsin and North and South Dakota. Salesrooms have been opened at 311 Third street South.

The International Harvester Co. has leased a two-story building at 1814-1816 Michigan avenue, Chicago, for a period of ten years. The premises will be used as display rooms for the trucks and delivery wagons made by the I. H. C.

The Matheson Motor Co. of Washington has been organized in the national capital to handle Matheson cars, and has opened showrooms in the Masonic Temple. Edmund K. Fox is president and Ernest H. Coolidge, manager, of the company.

The A. F. Kelsey Garage, in Shelbyville, Ind., which recently went into the hands of a receiver, has been purchased by John F. Day and Charles E. Arnold. They will continue the business under a new name, which has not yet been decided upon.

The Cedar Auto & Marine Co. has been formed in New Rochelle, N. Y., with Feuncll D. Franklin, of New York City, as president. A large fire-proof garage is being erected for the company in Cedar road and will be ready for occupancy on May 1.

The North Garey Garage, in Pomona, Cal., has changed hands, F. C. Howland taking over the business from E. W. Davies. The title of the establishment also was changed to Studebaker Garage. As the name implies, Studebaker cars will be sold exclusively.

Charles J. Parker and Alex Robertson have purchased the Western Motor Supply Co., 1018 Nicollet avenue, Minneapolis, Minn. Parker is manager also of the Tri-State Rubber Co., distributor of Swinehart tires, and will merge the rubber with the supply company.

L. D. McCarthy, distributor of Rambler cars in Spokane, Wash., has opened a branch in Walla Walla, where he will do business under the style of the L. D. McCarthy Automobile Co., of Spokane. The salesrooms are located at 105 Fourth street and are under the management of W. H. Wierman.

The Bowler Motor Car Co., which has the Cole agency in San Diego, Cal., has been reorganized and henceforth will be known as the Cole Automobile Co. Simultaneously with the change of name, the selesrooms of the company have been transferred to the property adjoining the Spreckels Theater building.

The Jandorf Automobile Co., successor to the Broadway Auto Exchange, has opened new showrooms at 42-44 West Sixty-second street, New York City, utilizing the old showrooms at 1761 Broadway for the display of bodies and tires. The factory and service department remains at Eleventh avenue and 58th street.

The Auto Livery Co. has been formed in Coffeyville, Kan., with E. L. Robinson, of the Robinson Packer Co., and Culbert Mason, of the Mason Auto Livery Service, as the moving spirits. The new company purposes to operate a general motor livery and renting service, with headquarters at the plant of the Robinson Packer Co.

Recent Losses by Fire.

Thorndale, Tex.—Thorndale Garage destroyed. Loss, $5,000.

Chicago, Ill.—Oak Park Taxicab Co.'s garage and five cars burned. Loss, $8,000.

Detroit, Mich.—Detroit Auto Garage, 68-70 Adams avenue, West, gutted. Loss, $35,000.

St. Paul, Minn.—C. W. Gordon's garage, 378 Summit street, and two automobiles burned. Loss, $7,000.

Mansfield, La.—Hernden Garage completely destroyed. Loss heavy; only partly covered by insurance.

Alpena, Mich.—Andrew Hanson's garage, on Washington avenue, destroyed. Loss, $1,500; covered by insurance.

Chicago, Ill.—Beckley-Ralston Co.'s sales room (automobile supplies), at 1428 Michigan avenue, destroyed. Loss, $5,000.

Increases and Decreases of Capital.

Chicago, Ill.—F. A. L. Auto Co., from $2,500 to $20,000.

Pittsburgh, Pa.—National Tube Co., from $9,000,000 to $13,000,000.

Wabash, Ind.—Service Motor Car Co., from $500,000 to $125,000.

Chicago, Ill.—Boulevard Motor Delivery Co., from $2,500 to $10,000.

Detroit, Mich.—Sewell Cushion Wheel Co., from $60,000 to $300,000.

Muskegon, Mich.—Muskegon Motor Specialty Co., from $30,000 to $100,000.

Philadelphia, Pa.—Standard Roller Bearing Co., from $5,000,000 to $8,000,000.

NEW YORK, APRIL 18, 1912

BEKNIGHTED VIEWS OF THE MOTOR STARTER.

Indications make it appear that the British idea of the motor starter is that its sole purpose is to eliminate the muscular effort required to start the motor, and that there is no particular reason for its use on a car driven by a chauffeur, because he is paid to work, or on a car driven by its owner, unless the owner is of a lazy disposition and objects to the "labour" involved.

That sometime American, Charles Y. Knight, who has learned to tickle the British fancy, encouraged the notion on the occasion of his recent return to London. He was interviewed, of course, and among other things American that were damned by faint praise was the motor starter. According to Mr. Knight it is popular here because such a large percentage of owners drive their own cars, because we are supplied with lower grades of gasolene, because our colder weather makes cranking difficult, because the average horsepower of our engines is much higher than those in use abroad, and so forth and so on, ad naus.

Perhaps these things were influential in popularizing the motor starter in this country, but any foreigner who believes that they represent the sum total of its advantages is either uncommonly short-sighted or is easily lulled to sleep. It may be true that desire to promote personal convenience by eliminating muscular labor was behind the first desire that gave us the device that permits starting the engine from the seat, but so many other and greater benefits have been found that the element of convenience has been, or soon will be, almost lost sight of. It prevents the fractured arms and sprained wrists that come of the deadly back-kick, and the even more serious results that come of cranking with gears in mesh; and these misfortunes are not restricted to America, and they are as painful and as expensive when inflicted by a car of 10 horsepower as by one of ten times that power, and whether the humble chauffeur or the lordly owner be the sufferer. In England, as in America, it is necessary to step into the street or road to crank a motor, and streets and roads are not always dry nor the skies untearful, nor are stalled motors in congested places or dangerous places unknown abroad; and presumably there as here anything that serves to make the motor car more "tractable" to womankind is to be encouraged; and among its many other virtues, the engine starter serves that purpose as nothing else can serve it.

Our English friends should undeceive themselves and cease to pander to their prejudices and to flatter their fancies. The engine starter is bound to attain universal use and they may as well join the march of progress and assist in its perfection.

SUPPORTING A CAR ON "NEXT TO NOTHING."

Periodically, some one or other attempts to show how it is possible to support an automobile on "next to nothing"—how a person with an income of $1,800 or $2,000 can maintain an automobile without, to employ the vernacular, "going broke." Whether or not these things are good for the industry or good for the man of moderate means is an open question. Certainly, before such figures and assertions are accepted at their face value they at least should be scrutinized carefully and pondered deeply.

The salaried man with an income of, say, $1,800 a year may be able to support a car without unduly straining his resources, but to do so every condition must be favorable. For instance, he must reside in a small city where rents are comparatively low, his garage must be his own property and he must drive the car himself; also he must be competent to care for the car—to make minor repairs and adjustments, etc. Then, if he has luck with his tires and other things, and if he has facilities for storing gasolene and lubricating oil, so that he can purchase them at quantity prices, it is quite conceivable that he can live within his income and drive his car very nearly as far as he has a mind to. But to suggest that a man with an $1,800 or $2,000 income can support a car in a large city like New York or Chicago, where garage charges and everything else come high, smacks of encouraging the sort of folly that leads to ruin and makes food for sensational newspapers.

Even assuming that the $1,800 man had been presented with his car, few compilers go so far as to present him with insurance also, and without it one bad accident would make a big hole in anyone's $1,800. The question is not whether a car can be maintained on $1,800 or $2,000 a year, but rather how it can be done. and though the odds are very much against a credit instead of a debit showing on the books of those who attempt it in a large city, where dependence must be placed on public garages, it is quite within reason that a mechanically inclined man without a mania for speed, can support a car without going bankrupt, on even $1,800 a year, provided he is his own driver and garage man and middleman in the purchase of supplies, and provided, also, that no one or nothing else is dependent on him for support. Indeed, so many provisos and ifs and other qualifications enter into the subject that for the general good it best had be left alone.

TIRE PRICES AND THEIR TROUBLES

New York Dealer Discusses Subject and Places Blame on Manufacturers—"Wildcatters" Who Promote Cutting.

"It may be that the list price of tires has constituted a huge joke—in fact, there is not very much doubt about it; but it does seem to me, now that they have been reduced, that the joke is being made too funny when the manufacturers endeavor to prove to jobbers and dealers that the reduction will permit them—that is, the jobbers and dealers—to make more money than ever before," was the rather caustic criticism of a New York dealer who has been identified with the tire trade for many years, and whose views regarding the price situation were sought.

"The tire makers have reduced prices and raised them, only to reduce them again, and always the reduction has meant less money for the jobber and dealer, despite the fact that, as in the present instance, we are asked to believe that such reductions are designed to check price-cutting and thereby enable us to increase our earnings. Some of us at least have cut our eyeteeth, and we decline to accept such professions at their face value; we believe we have ample justification for doing so.

"Perhaps the tire manufacturers have meant well, but it seems as if their prices have been made only to be cut, and conditions are such that no price they now may name will serve any other purpose. I cannot recall a time during recent years when any car owner, who was not sound asleep, paid full price for his tires. The price cuts have been horizontal, and vertical, and of every other sort; in fact, prices have been simply cut to ribbons. Manufacturers know it as well as anyone else, but pinching our discounts close behind the ears will not serve greatly to clarify the situation. The new prices already have been cut as freely as the old ones, and they will be cut again so long as the tire manufacturers continue their present policy of giving trade discounts to anyone who brings a letterhead or a business card to prove that he is a dealer or a jobber. Perhaps they cannot stop the cutting, but the practices of many of the tire manufacturers themselves are not above suspicion and criticism, and it seems to me that the present is a pretty good time for plainly speaking on that score.

"It is a fact, and one that is susceptible of easy proof, that a business card or a letterhead is practically all that is necessary for any man to secure trade discounts, and when I say 'trade discounts' I mean the preferred quotations. It is not so long ago that those of us who are doing a legitimate business were assured by at least some of the bigwigs in the tire trade that preferred discounts would be accorded only to a certain number of dealers and jobbers whose standing was beyond question. In New York, if I remember rightly, the number was fifty-nine. Apparently, however, these assurances soon were forgotten, and it has appeared as if the owner of a mere hole in the wall is not too small to be denied these figures. No one seems to have had any great trouble in getting them, and the tremendous multiplication of tire dealers and tire jobbers and the consequent wholesale slashing of prices are the direct results of that policy.

"I know one chap, a ne'er-do-well, who went into the tire business with a capital of $35. He hired a hole in the wall, printed a letterhead and hung out a sign proclaiming that he was in the business of selling and repairing tires; and, although he had not more than three sticks of furniture in the place, he secured the preferred prices, apparently, without quibble and without question. With his capital in hand he purchased one tire, sold it at a good profit, and turned over the money to such good purpose that at the end of three months he had cleared more than $700. The sales were made at a cut price—he could do business in no other way—and he never repaired a tire in the course of his existence. All the jobs of that sort which he secured he sent out and had performed by such people as ourselves, who maintain repairing and vulcanizing plants. Although on the road to at least modest riches, the ne'er-do-well's habits were too strong, and he fell back again into his old ways, and his money and his 'tire business' went with him.

"There are several chauffeurs who have embarked in the tire business in about the same way. They paid $20 or so for a vulcanizer, printed a letterhead and set up in business. By sharing their discounts with other chauffeurs—at the car owner's expense—they have swollen their incomes to proportions of which they once dared not dream.

"In some cases not even a hole in the wall or a cheap vulcanizer is necessary to secure the discounts. There is one shrewd individual, located in one of the much-peopled buildings within sight of Central Park, whose only visible asset is a desk, occupying part of an office with other desks. He calls himself a company, however, and possesses a letterhead, and he, too, is considered in the tire business and is accorded the preferred figures. His expenses are practically nothing and he carries no stock whatever; indeed, he has no place to carry stock. All he does is to purchase tires from the manufacturers' branches and deliver them when he obtains an order. I understand, and I have every reason to believe it is a fact, that, while he gets more when he can do so, this alleged 'company' is satisfied with a margin of 2½ per cent. profit.

"These are no dreams; they are actualities; and when such conditions exist, and when they are to blame for them, how can the tire manufacturers expect to lessen price cutting, much less stop it? They actually force those of us who are doing a legitimate business to compete with such people. Why should we turn anyone from our doors, when we know that the chances are strong that they will get what they want from the 'wildcatters,' who have grown up by grace of the tire manufacturers themselves?

"Of course, the latter will maintain that they cannot control the price of an unpatented article, but they hardly dare say that they cannot require that certain conditions be fulfilled before granting their best discounts. They all seem fearful that somehow some small portion of the business will get away from them, and they act accordingly, and then protest more or less conscientiously when people situated as we are similarly decline to turn trade from our doors.

"We have a considerable establishment to maintain and a considerable payroll to meet; we always have on hand several thousands of dollars worth of tires; we run a repair and vulcanizing plant that is second to none, and yet in the eyes of the tire manufacturer, apparently, we are no better than the man who merely has a letterhead, a hole in the wall, and who can do business on next to nothing. While the tire manufacturers are seeking to place the blame for existing conditions, they should look in the mirror and place much of the blame where properly it belongs—on themselves."

April 15-20, Birmingham, Ala.—Track races under the auspices of the Birmingham Automobile Dealers' Association.

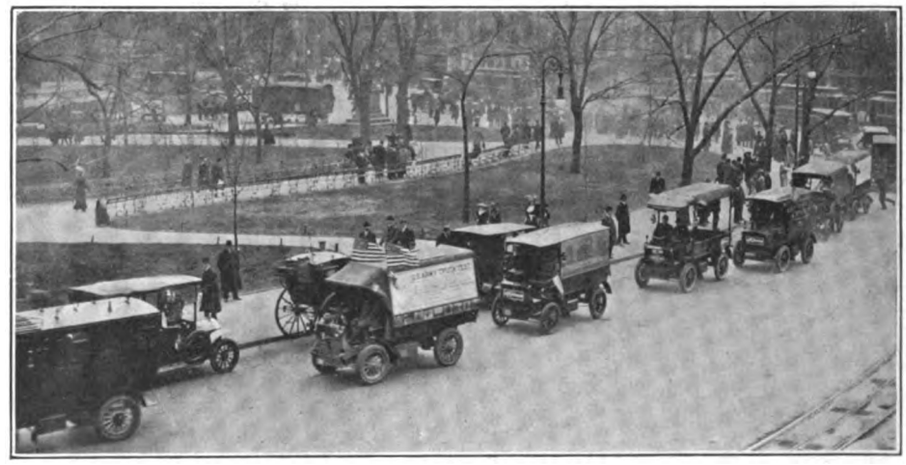
TRAFFIC HINDERED TRUCK PARADE

New York's Turnout Proves Better Than First Effort but Still Lacking—Splendid Contrast of Types.

Just as the word "turnout" fitted the rather disjointed procession of motor trucks which a year ago about this time chugged its way up and down Broadway and Fifth avenue better than the word "parade," which was the official designation given the function by its sponsors—the Motor Truck Club, of New York City—so it fitted on Saturday, 13th inst., when the second annual "parade" wended its way from Battery Park by a more or less devious route to 125th street and Broadway, where the trucks were dispersed.



GENERAL VEHICLE BATTERY CRANE TRUCKS THAT DREW ATTENTION

In other respects it resembled its prototype of a year ago, too. Though the weather was not quite so bad as it was for the first parade, dark clouds obscured the sun and the weather man threatened "local showers," which perhaps accounts for the slim crowd that ceased its toil long enough to watch the procession. In fact, it did sprinkle a little bit, though not enough to cause the official band, ensconced on the hurricane deck of a Fifth avenue bus, to seek shelter inside, as it was compelled to do last year. Down at Battery Park and on lower Broadway, where the procession started—it was scheduled to move at 1:30 p. m., but failed to get under "weigh" until 2:30—a fair-sized crowd lined the curbs and watched the big trucks and little trucks and medium-sized trucks move off toward their destination. As the procession rolled uptown, however, the crowds grew steadily slimmer, until even at 50th street and Broadway, which was about two-thirds of the whole distance traveled, the knots of spectators which gathered here and there on the sidewalks could hardly be called crowds, individually, or a crowd collectively. The streets were not cleared for the paraders, and when they mingled with the dense traffic on Fifth avenue the procession became disjointed, if not disorganized, and was lost in the maze, so to speak.

According to the plans of those to whom was allotted the routing, the procession was supposed to proceed directly up Broadway to 125th street, except that a slight detour, around what has been styled the "matinee district," would take the trucks off the White Way for a few blocks. The line of march, therefore, led up Broadway to 22nd street, where the trucks were switched over to Fourth avenue for a short run up to 27th street, and then through to Fifth avenue. From there the procession was steered to 48th street and through to Broadway again.

And there were plenty of places that were not good locations from which to view the procession. Contrary to the expectations of those who gathered there, and also contrary to the route as originally mapped out, Broadway and 48th street was one of those locations. The advance of the procession reached there about 4 o'clock, and all went well for about fifteen or twenty minutes, or until approximately 100 trucks had passed. Then there was a cessation of activities, and it was supposed that the whole number of trucks had passed. Which lends point to the assertion that few had heard anything about the "parade." At any rate, those who had foregathered went their way, and it was not until several minutes later that the procession was noticed going through other streets—any other street than 48th, it seemed—and regaining Broadway above 50th street. Eventually the stream was turned back into 48th street, but those who waited there missed quite half of it.

In respect to strength of numbers, the procession was considerably larger than last year's. Whereas only some 200 trucks formed in line last April, on Saturday the number by actual count was 344. Following the general rule of the previous event, the trucks were formed in line at the Battery in alphabetical order, according to their trade names. But, as was the case last year, they did not remain in that order for a very great length of time, and the further uptown the procession got the harder it became to determine exactly where the ordinary everyday traffic left off and the "parade" began, or vice versa. When the same trouble was encountered last year it was planned to overcome it this year by instructing the drivers to "stick together"—to wait for each other—but the traffic regulations played havoc with the line, and the instinct to "beat it" was just as strong in the breasts of some as it was a year ago. In fact, nearly all the drivers seemed bent on covering the course in the shortest possible space of time, and it was suggested that some of the trucks must have had their speed-governing devices temporarily unsealed. At any rate, it so appeared to those who watched the trucks almost literally fly past, and it was not long before the original three divisions which started from the Battery were split up into nearly ten times that many.

AT UNION SQUARE, WHERE THE PARADE MAINTAINED ITS FORMATION

But as fast as some of the trucks were driven, they still afforded a prime chance for their owners to advertise either the trucks or the merchandise which they carried, or the owners themselves. Every entrant was permitted to load his truck with whatsoever he willed, and nearly every one of them took advantage of the privilege. Brewery trucks, heavily laden with what

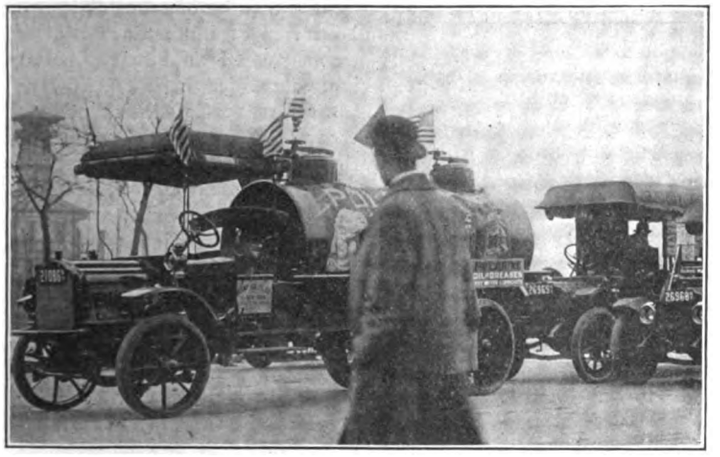
NEW YORK TRUCK PARADERS LINING UP FOR THE START FROM BATTERY PARK

Digitized by Google

appeared to be beer—the kegs were there, anyway—sped past; furniture vans piled high with furniture, and all manner of other vehicles loaded to the "gunwales" were included in the moving display.

The honor of having the greatest number of trucks of the same make en route went to the Autocar Co., of Ardmore, Pa., as represented by the Autocar Sales Co., of New York, which had upward of forty trucks, all bearing the Autocar name-plate, in the procession. The United States Motor Co. was next with some twenty-three Sampson trucks, and the General Motors Co. was third with twenty G. M. C. trucks. These were the largest delegations of single makes, though there were others, notably the International Motor Co., which had ten Mack trucks and six Saurers of varying capacities, which were well represented. For instance, there were seven Couple-Gear trucks up at the head of the procession—by reason of their size they looked to be more than seven; there were about a dozen Alcos and a similar number of both Packards and Pierce-Arrows. Walter trucks were well represented, and so were White, Pope-Hartford, Knox, Garford, Knickerbocker, Gaggenau, Federal, Chase and any number of others. But the procession was not made up entirely of gasolene trucks, though they formed a considerable portion of it. Electrics were very much in evidence. The General Vehicle electrics in particular were conspicuous, there being no less than thirty-eight of them in line. Among the other makes of electrics that turned out, Hupp-Yeats, Baker, Detroit and Bronx were represented.



WHERE THE BAND PLAYED

Though there was little that was spectacular about the "parade," decorations of any kind being conspicuous by their absence, there still was plenty to hold the attention of the onlookers. Up at the head of the procession the Autocar army truck, which recently completed a strenous 1,500-mile trip from Washington to Indianapolis, and which still carried liberal quantities of mud, caused comment. The Knox Martin tractor was another vehicle which drew attention; but the ones that excited the most curiosity were the General Vehicle battery crane trucks. These little vehicles, scarcely a quarter the size of most of the other trucks in the procession, are intended for the rapid handling of heavy merchandise, and speeding silently along with the van, their cranes being their most conspicuous feature, never failed to attract and to hold attention as long as they were in sight.

In all, there were upward of fifty different makes of vehicles in line, and though the trade was well represented, for the most part the trucks were the property of private owners or corporations, bent on displaying to the general public their up-to-date equipment and the facility with which merchandise destined for long or short hauls can be handled. And whatever else the procession may have shown, it at least demonstrated the ease of handling motor trucks in congested traffic, the loads which can be hauled as compared with those which can be transported by means of horsed vehicles, and the greater speed in distribution which is possible with modern motor-propelled apparatus.

E. W. Curtis, Jr., was chief marshall, and headed the procession riding in an electric coupe. C. W. Fletcher and T. A. Aspell acted as chiefs of division, and the other aides were as follows: G. M. Curran (International), D. D. Robinson (Baker), R. R. Clayton (Studebaker), H. C. Brown (Sampson), F. B. Kutz (Pierce-Arrow), E. A. Bedell (B. F. Goodrich Co.), N. Mallouf (Peerless), P. J. Dougherty (Anderson), F. W. Dix (Pope-Hartford), C. W. Wurster (Commer), J. M. Young (Chase), M. J. Adams (Alco), J. L. Breese, Jr. (Commer), G. E. Anderson (B. F. Goodrich Co.), E. O. Hoopergarner (Swinehart), A. L. Barringer (Sampson), G. L. Moore (Swinehart).

Automobiles Factors in "Race Suicide."

How an automobile could be guilty of, or an accessory to, race suicide is rather difficult to understand, but Professor Robert J. Sprague, of Amherst College says so, and he claims he has the proofs. According to the professor automobiles and oriental rugs are the chief things that keep wealthy—or medium well-to-do—people from having children. They love—still according to Profesor Sprague—the speeding motor car more than children, and the human race is the loser.

FEDERAL AID GETS SLIGHT BOOST

Congress Committee for First Time Favorably Reports a Bill—But It's a Makeshift and Helps Little.

While the bill introduced by Congressman Shacklefield, of Missouri, and favorably reported late last week by the House Committee on Agriculture, is at best but a makeshift, it is important as being the first of the many Federal "aid" bills to make such progress. The Shacklefield bill, while not enthusiastically supported, is at least not opposed by the automobile interests of the country—not because it is a particularly good bill, or because it represents a solution of the question of Federal aid, but because it is the best that has been offered so far. If it were passed it would serve chiefly to promote widespread and thinly-spread road tinkering, instead of real improvement; but its passage, despite the House Committee's approval, is wholly unlikely.

The measure makes provision for a prorata payment for the use of State or County roads by Federal employees (letter carriers on rural free delivery routes), and for this purpose divides the roads into three classes—A, B and C. As the bill provides for compensation only in the case of roads of certain quality, which fulfill the requirements of the government, it is claimed by the supporters of the bill that it will result in immediate activity on the part of communities in which the roads are poor, in order that they may collect compensation claims. An "estimate" of the road rental which the State of New York or its counties could collect for the first year from the government under the provisions of the Shacklefield bill, fixes the amount at about $650,000.

The full text of the bill is as follows:

That for the purposes of this Act certain highways of the several States, the civil subdivisions thereof, and companies incorporated under the laws of the several States are classified as follows:

Class A shall embrace well-graded roads outside of incorporated cities, towns, and villages of not less than one mile in length, upon which the steepest incline shall not exceed five per centum wherever practicable, not less than twenty-five feet wide between the ditches, well drained, with a wagon way or road track not less than twelve feet wide, composed of bituminous macadam, brick, or of macadam, not less than six inches thick, rolled, bonded, and maintained with a smooth, firm surface, both shoulders and roadway properly constructed and continuously cared for.

Class B shall embrace well-graded roads outside of incorporated cities, towns, and villages of not less than one mile in length, upon which the steepest incline shall not exceed five per centum wherever practicable, twenty-five feet wide between the side ditches, well drained, with a wagon way or road track twelve feet wide, composed of burnt clay, shells, sand, clay, or gravel, not less than eight inches thick, continuously kept well compacted, and with a firm, smooth surface, with roadway well and properly crowned, so as to quickly shed water into the side ditches.

Class C shall embrace roads outside of incorporated cities, towns and villages of not less than one mile in length, upon which the steepest incline shall not exceed five per centum wherever practicable, which shall be kept well graded, crowned, and drained to a width of not less than eighteen feet, with split-log drag or other similar means, so as to be reasonably passable for wheeled vehicles at all times.

Sec. 2. That whenever the United States shall continuously use any highway of any State, or civil subdivision thereof, or of any company incorporated under the laws of any State, which fall within classes A, B or C, for the purpose of transporting free rural-delivery mail, compensation for such use shall be made at the rate of thirty dollars per annum per mile for highways of class A, twenty dollars per annum per mile for highways of class B, and ten dollars per annum per mile for highways of class C. The United States shall not pay any other compensation or toll for such use of such highways than that provided for in this section, and shall pay no compensation whatever for the use of any highway not falling within classes A, B or C.

Sec. 3. That the Director of Roads in the Department of Agriculture shall determine the class, if any, into which any road shall fall, and his determination upon that subject shall be final.

Sec. 4. That the compensation herein provided for shall be paid at the end of each fiscal year by the Treasurer of the United States upon warrants drawn upon him by the Postmaster General to the officers or persons entitled to the custody of the funds of the respective highways entitled to compensation under this Act.

Sec. 5. That this Act shall go into effect on the first day of July, nineteen hundred and thirteen.

Jersey Chauffeurs Become "Associated."

With the announced intention of "raising the standard of the men employed in operating motor cars in New Jersey and conserving the interests of the employer," an organization of professional chauffeurs has been launched in Newark, N. J., under the style Associated Motor Operators. Temporary quarters have been engaged at 313 Halsey street, where the first organized meeting was held on Monday last, 15th inst. Thirty-three charter members attended the meeting and elected the following officers to serve for the next six months: A. H. Langdon, president; A. C. Haughawant, vice-president; W. K. Donaldson, secretary; E. G. Filtz, treasurer; J. Heaver, sergeant-at-arms; William Brooks, C. E. Bentley and H. L. Greenough, examining committee.

Hail "Agrimotors" and "Autoporters."

In the straining for originality they achieve some fearful results on the "other side." One of the automobile publications, for instance, is endeavoring to popularize "agrimotors" as a descriptive of steam plows, gasolene tractors and other vehicles designed for the emancipation of the farm horse, and is applying the term "autoporters" to vehicles used for light delivery work, such as tricycles.

"ELEPHANT" ON UNCLE SAM'S HANDS

It's a Britisher's Automobile Seized More Than Five Years Ago—Commission to Settle Date of Purchase.

"The United States vs. One 30-Horsepower Automobile" is the title of an action which is on the current calendar of the admiralty division of the United States District Court for the Southern District of New York. Behind the somewhat mystifying title there lies an apt illustration of the law's delays and a tale of six years of adventure experienced by a 30-horsepower C. G. V. car of the vintage of 1905, which for eleven short months was the property of one James Pearce, of London, England, but which for the past five and one-half years has been reposing peacefully in one of the many storehouses in which Uncle Sam keeps the thousands of articles he confiscates annually from "forgetful" travelers.

The case seems to involve at least one consul-general and to be of more or less international interest or importance, and apparently grows out of an alleged mistake in the shipping invoice made out by the London Motor Garage Co., which originally sold the car to Pearce, on September 6, 1905, for the sum of £860. When Pearce came to visit America, on October 24, 1906, he declared in good faith, and upon the particular advice of Consul-General Wynne, that he was a non-resident and that the automobile had been used by him and his family for one year. A cursory examination of the shipping records and bill of sale for the car, however, showed that it had been shipped to Pearce, who at the time was in Paris, on November 1, 1905, and not in September, as he claimed. This date would make the time of the car's "servitude" less than eleven months, instead of the full year sworn to by Pearce. Thereupon the customs officers at New York promptly confiscated the car.

Pearce made several attempts to have the matter adjusted, but lost out each time, until last May, when he petitioned the court to appoint a commission of four prominent Englishmen, who were to be authorized to take testimony on the other side regarding the exact dates of sale and shipment of the car. The United States court granted the motion and the commission was appointed last summer. What its members discovered probably will be told in the hearing which has been set for this week before Judge Hough in the Federal court.

Mayor Favors City License for Trucks.

According to a bill which has been introduced in the Ohio legislature, at the suggestion of Mayor Helmbold of Cincinnati, motor wagons used for commercial purposes are to be licensed by cities, regardless of what disposition the State automobile law makes of them.

CENSUS DISCLOSES MORE DETAILS

Latest Preliminary Report Particularizes Nature of Automobile Output—How It Compares With Horse Vehicles.

Having presented statistics of the automobile industry in two previous reports, the United States Census Bureau has issued what is styled the "second preliminary report," which permits the industry to be viewed from still another angle. While the totals are the same, it differs from the previous documents in that it separates the various types of vehicles, enumerates the number produced and the value of each, which enumeration will serve forever to settle considerable speculation which has existed.

The report, of course, covers the five-year period 1904 to 1909, during which the production leaped from 22,830 cars to 127,287 Previous to 1904, automobiles were included in the general statistics of carriage and wagon manufacture, the number of purely automobile factories being too insignificant to constitute an industry. In 1899, according to the Federal figures, there were produced only 3,897 vehicles, so that the total for 1909 represents a gain of approximately 3,300 per cent. in the period of ten years. The value of all products of the automobile industry proper, as already made known by the previous preliminary report, was $249,202,075 in 1909, as against $30,033,536 in 1904; but the Census Bureau points out that under the designation "All Other Products" are included the products of establishments engaged in the manufacture of automobile bodies and parts which were sold largely to automobile manufacturers, as well as the bodies and parts made and sold separately by automobile manufacturers.

Gasolene machines formed 95.1 per cent. of the total number made in 1909, and 86.2 per cent. 1904. Of the total number manufactured in 1909, 3,226, or 2.5 per cent., were rated at 50 h.p. or more; 51,218, or 40.5 per cent., at from 30 to 49 h.p.; 35,257, or 27.8 per cent., at from 20 to 29 h.p.; 29,353, or 23.2 per cent., at from 10 to 19 h.p., and 7,539, or 6 per cent., at less than 10 h.p. Passenger vehicles constituted 97.4 per cent. of the total number, and business vehicles 2.6 per cent.

The "second preliminary report" of the carriage and wagon industry, which serves to show the inroads that have been made on the horse vehicle during the census period of five years, naturally is of value to the automobile trade and will assist reckonings of future probabilities. While the valuation of horse vehicles did not decline in corresponding proportion, the number in each instance fell away approximately 100,000 vehicles in the case of both carriages and wagons. The figures for both industries are shown in detail by the accompanying table.

STATISTICS OF THE AUTOMOBILE INDUSTRY, 1904-1909

DISBROW LOWERS THREE RECORDS

On San Jose Track He Displaces Oldfield's Figures—Completes Twenty-five Miles in 22:26⅗.

Louis Disbrow, who, under the active management of J. Alexander Sloane, has been emulating the one-time efforts of his redoubtable predecessor, Barney Oldfield, and has been treating the natives of the Pacific Coast to some fast track driving, again appeared at a local meet on the San Jose (Cal.) Driving Park course on Sunday last, 14th inst. Discarding his latest and fastest speed creation, the 190 horsepower reconstructed Fiat, which has been styled the "Jay-Eye-See," he held the wheel of Ralph De Palma's 90-horsepower Simplex and drove to such good purpose that he is credited with having shattered the 15, 20 and 25-mile records which have been held by Oldfield since September, 1910.

Inasmuch as the meet was held under sanction of the American Automobile Association, and as Disbrow was clocked under the supervision of P. J. Walker, who is the Pacific Coast representative of the A. A. A., the records must be accepted at their face value, at least until such time as the Contest Board can pass on them and determine whether the conditions governing the establishment of records have been complied with. Despite the fact that the track was not in the best of condition owing to continued rains, Disbrow made 15 circuits in 13:30, 20 in 17:57⅘, and 25 in 22:26⅗. According to the records, the best previous time for these distances was made by Oldfield in Milwaukee on September 27th, 1910. Oldfield's times were, 13:41.40, 18:15 and 22:47, for the three distances, respectively.

Where Joy Riders Lose Their Licenses.

By issuing an executive order the government of the kingdom of Wuerttemberg, Germany, two months ago endeavored to curb the growing tendency of chauffeurs to use their employers' cars for "joy-rides." As was pointed out in the Motor World some months ago, the German law fails to make provision for punishment of people using another person's car without permission, excepting that gasolene and oil belonging to the owner of the car have been used on the ride. It was found that the passage of such a law would entail so much lost time, that the officials of Wuerttemberg decided to employ the short cut of an executive order coming direct from the ministry of the interior. According to this order any chauffeur who is detected in using his employer's, or any other man's, car without special permission, loses his license and cannot have it restored at any future time. This severe punishment, in the few weeks that it has been in effect, has been so successful that the Bavarian government last month took similar action. The other German States are expected shortly to issue and promulgate similar orders.

St. Louis Speed Law Held Valid.

In an opinion delivered in a damage suit instituted by Catherine Steinlage against Charles Wiegand for the wrecking of the former's automobile, Judge McQuillin, of the Missouri State Court in St. Louis, decided that the city ordinance limiting the speed of automobiles to 10 miles per hour is valid, despite the fact that the State law fixes 25 miles as the permissible limit. In his ruling the judge declares that the State law does not mean that a lower rate of speed than 25 miles an hour would be conclusive evidence that the motorist was driving in a "careful and prudent" manner, as the automobile law requires, and that he was not guilty of preventive negligence. The attorney for the defendant had contended that owing to the conflicting wording of the city ordinance and the State law, the former should be held invalid, and that the damage suit should be dismissed, as being based on the violation of an invalid ordinance.

Wants $10,000 for Pain and Lost Titles.

Claiming that an accident to her automobile on the streets of Cleveland, O., robbed her of her titles as tennis, skating and whist champion of Canada, Mrs. Annie C. Burgess, of Toronto, Can., has filed suit in the Ohio Supreme Court, in Cleveland, against Rinehart Bros., paving contractors of New Lisbon, O. According to her complaint, Mrs. Burgess was attending the State tennis tournament at Cleveland when the accident occurred, and her automobile ran into an excavation of the street, which, it is alleged, was not protected by red lights. She received injuries in the accident which, she claims, prevented her from taking part in the annual championship tournaments of Canada and defending her various titles. She values this loss, coupled with the bodily pain in having her wrist and ankle wrenched, at $10,000.

Corning Motorists Organize a Club.

The Corning Automobile Club has been organized in the New York town of that name, with the following officers: H. H. Kendall, president; M. E. Gregory, vice-president; F. P. White, secretary, and Winfield C. Sleight, treasurer. The board of governors comprises John L. Lewis, John M. Pitt, W. J. Tulley, H. L. Holluster, Charles Githler and Dr. C. F. Buckland.

Case Heads New Club in Peoria.

E. J. Case has been elected president of the newly organized Peoria (Ill.) Automobile Club. The others officers are: W. C. Collins, vice-president; C. E. Ulrich, secretary-treasurer. The directors are: W. E. Hull, W. C. Roberts, Thomas H. Webb, R. H. Johnson, Carl Block, Dr. F. B. Waugh, H. B. Pinkerton, H. G. Herget, S. K. Hatfield and D. Nelson.

INDIANA SPEED LAW NULLIFIED

Court Holds That "Closely Built-up Portions" Clause is Too Vague—Victory for Two Chauffeurs.

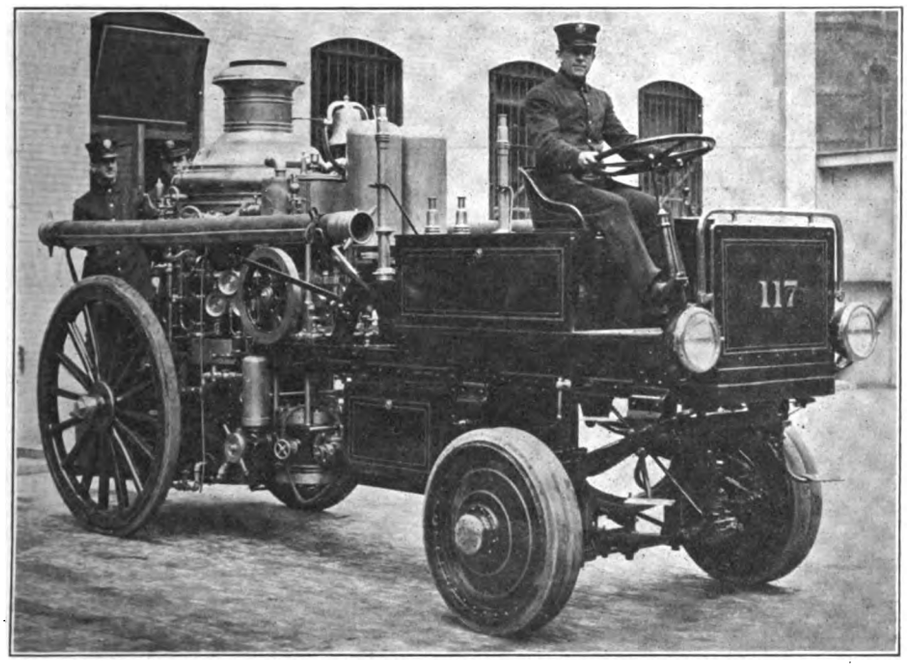
Although the report repeatedly has spread that the automobile laws of Indiana—and, by inference, those of other States—are unconstitutional because of the vague wording of the clause regarding the "closely built-up portions" in which the speed limit is restricted, judicial confirmation of the alleged unconstitutionality had been lacking. Last week, however, the Circuit Court of Appeals of Indiana, in reversing the decision of the lower court in the cases of two chauffeurs, Walter Johnson and W. Ottman, ruled that no prosecutions for violating the speed limit can be made, as the law is unconstitutional. The court held that the definition, "in the business and closely built-up portions of any municipality" is too vague to allow of embodiment in a valid law or ordinance. The paragraph declared invalid is as follows:

"Any person or persons operating a motor vehicle on any public highway or in any public place shall not operate the same at any rate of speed greater than is reasonable and proper, having regard for the use in common of such highway or place, or so as to endanger the life or limb of any person, and in no event shall such motor vehicle be operated at a greater rate of speed than eight miles an hour in the business and closely built-up portions of any locality."

To Repeat the Four States Tour.

July 9th has been fixed as the tentative date for the start of the second annual Four States tour, under the auspices of the Indiana Automobile Manufacturers' Association, which was inaugurated last year, chiefly to boom Indiana products in that State and in three States adjacent thereto. On the forthcoming occasion, the route will be laid through Indiana, Ohio, West Virginia and Kentucky, and the contest will last about 15 days. The rules will be as easy as those of last year, the competitive feature of the event being of a merely nominal nature. Long stops will be made in all of the promising towns en route and the citizens thereof be given a good look at the cars and an ample supply of advertising literature.

Car With a Record of 135,000 Miles.



To the oft-asked question, "How many miles will a car last?" Harry Vissering, president of a Chicago railway supply company, is the latest to make answer. He avers that his 40-horsepower Alco car, purchased in 1907, has been driven 135,000 miles, and though twice upset in ditches, still is in service, having suffered no serious damage. Incidentally, the last pair of rear tires lasted for 10,000 miles.

NEW YORK'S ELECTRIC FIRE FIGHTER

First "Steamer" Adapted to Electric Propulsion Goes Into Service—How the Conversion Was Brought About.

As is perfectly right and proper, the Fire Department of the City of New York has a rooted objection to throwing away perfectly good steam fire engines that cost $6,000 apiece, even to make room for motor propelled apparatus. But the department is being gradually and surely modernized, and the engines cannot be allowed to lag behind in the general progress. Therefore, with a view to making a compromise between needless expense on the one hand and lack of progressiveness on the other, the department has for some time been making experiments with converted steamers, utilizing the entire steam pumping plant and adding a propelling mechanism.

COUPLE-GEAR BATTERY DRIVEN CONVERTED FIRE ENGINE

The first tentative experiment consisted of attaching a steamer to a Couple-Gear tractor and hauling it around the streets to get an idea as to how the engine would lend itself to this means of propulsion; but nothing further was done in this direction. Soon afterward, an engine was converted by the Nott fire engine company by building in a gasolene motor of 110 horsepower, driving the rear wheels through a complicated system of shafts, bevel gears and sprockets. Though capable of great speed, this machine has been out of service and in the repair shop much of the time, owing to the enormous weight of the engine and transmission system. A few weeks ago the Christie front-drive system was applied to an engine, and the resulting machine was illustrated and described in the Motor World at the time of going into regular service. This engine and its novel propelling mechanism have given splendid satisfaction, never having missed an alarm and always being ready to respond to the very frequent calls in the busy district where it is stationed.

The third converted engine differs from both the others in that it is electrically driven, but resembles the Christie in that it drives through the front wheels. The conversion was made by the Couple-Gear Co., of New York, by installing a pair of Couple-Gear wheels with enclosed motors and a battery to furnish the current. As the illustration shows, the result is a decidedly sightly machine, and one of its characteristics is that it moves practically without a sound; in fact, it is so quiet when in motion that it is difficult to realize that it is not coasting. It is believed that this is the first time a fire engine has been "motorized" by the use of electric propelling apparatus.

The control of an electric vehicle is simple in the extreme, but special pains have been taken to reduce the control system of the big fire engine to the very last point. A controller of the street railway type gives five speeds forward and five in reverse, and is mounted at the left side of the single bucket seat; but it is used only when starting and after stopping, speed control on the road being effected through a pedal. In starting, the controller is thrown forward a notch at a time until it is on the high speed point. After that the driver presses forward the control pedal to maintain the speed, and if allows the pedal to return under pressure of its spring the speed will be reduced by degrees, until at the point where the pedal stops the current is cut off from the motors. This pedal is controlled by the left foot, while the right foot takes care of the brake, so that the driver has both hands free to steer with. The foot control of the current is effected through a resistance. When all the resistance is out and the motors are getting full current, the machine will run twenty miles an hour, and any intermediate speed can be obtained by the use of the resistance.

The battery consists of 80 cells of National thin-plate type, 11 plates to each cell, and gives the machine a radius of about twenty miles on one charge, which is, of course, considerably more than it is likely to require at any time in regular service. weight is almost equally distributed on all four wheels, the rear wheels carrying about 400 pounds more than the front wheels. Gibney 3½-inch dual tires are fitted to the 36-inch front wheels, the rear wheels already having solid rubber tires.

After having undergone a number of preliminary road tests, the engine, No. 117, was yesterday sent to its post at the Jay street station, in Brooklyn, where its ability to do real work in the service of the department will be thoroughly tried out.

King's Skeleton Paraded in Western City.

An animated skeleton has been running around the streets of Milwaukee, Wis., of late, and though the sight was an unusual one, it created no alarm even in the most timid, for it was the skeleton of a motor car—a King. The local agents, Eustis Bros., hit upon this method of showing just how every part of the mechanism worked. Everything was removed except those parts necessary to the operation of the machine—even the driver's seat went, to be rplaced by a mere box, and the gasolene tank gave place to an ordinary one-gallon can. All the parts were marked with their names in plain letters, so that he who saw the car run might read. While body-less chassis often have been seen in the streets, this probably is the first time the idea has been carried to the limit and made use of for advertising purposes, and doubtless it will not be the last, for the scheme apparently worked well and attracted no end of attention.

End of Muffler Cut-Outs in New York.

For some reason, Mayor Gaynor, of New York, did not see fit to attach his signature to the ordinance passed April 3rd by the Board of Aldermen, prohibiting the use of muffler cut-outs. As he failed to disapprove it, however, the ordinance automatically became a law on Saturday last, 13th inst. In accordance with its terms, however, it will not become effective until 90 days hence.

Guarantees Cars Against Fire and Theft.

In Spokane, Wash, at least, one of the most prominent dealers is now selling his cars with a one-year guarantee against fire and theft. He is Harry L. Olive, who handles Overland and Thistle cars.

MAKING PLAIN MAGNETO'S WORKING

One of the Several Demonstrations Employed by the Remy Company—Proof of Sparking at Low Speeds.

Dark as the subject of ignition may be to the average man of non-technical proclivities, it is doubtful if he could view the demonstration employed by the Remy Electric Co., of Anderson, Ind., and go away without knowing at least what a magneto spark looks like, and, what is more to the point, exactly what it looks like when it occurs in the cylinder of an engine at the instant the explosion takes place. For that is exactly what the demonstration is arranged to show and it shows it in a manner that is more than ordinarily clear.

The principal purpose of the whole demonstration, of course, is to display some of the better known Remy products in actual operation, and no less than five magnetos, all different—four of them being new types—are shown generating long sparks and short sparks and fat sparks, but they are all hot sparks. From left to right the five magnetos in the picture as as follows: Type 1912 S, for automobiles; type RG, double distributor tractor magneto; type RF, for heavy duty motors and tractors; type RE, double distributor automobile magneto; and type RD, which is the well known four-cylinder automobile motor instrument. One of the real features of the exhibit is what has been styled the "hot spark at low speed test," and it has been arranged for the particular education and edification of those who may perhaps doubt the ability of a magneto to deliver a really hot spark at very low speeds. The plugs are fixed in air-tight glass chambers, into which air under 100 pounds pressure is injected by means of a force pump. When the armature of the magneto is rotated at speeds of even less than 100 revolutions a minute sparks passing between the electrodes of the plugs are plainly visible.

DEMONSTRATING THE OPERATION OF REMY MAGNETOS WITH THE AID OF "BOTTLED" PLUGS

Funnel That Facilitates Filling Operations.

It is not always easy to fill a gasolene tank holding a funnel with one hand and the gasolene can with the other. The difficulty may be overcome by soldering three "legs" to the rim of the funnel so that it will stand alone with the small end projecting into the tank. If the "legs" are of the proper length, this method of treating the funnel has the additional advantage that an air space is left between the small end of the funnel and the filler hole in the tank, the result being that the tank may be filled more rapidly and with less danger of the fuel slopping out. Obviously the method is most applicable where the gasolene tank is located under the front seats and the top is level, though with a little ingenuity the "legs" can be so constructed and arranged that the funnel will be held in position over almost any tank filler hole, no matter what the location of the tank may be.

When Pumps May Act as Obstructions.

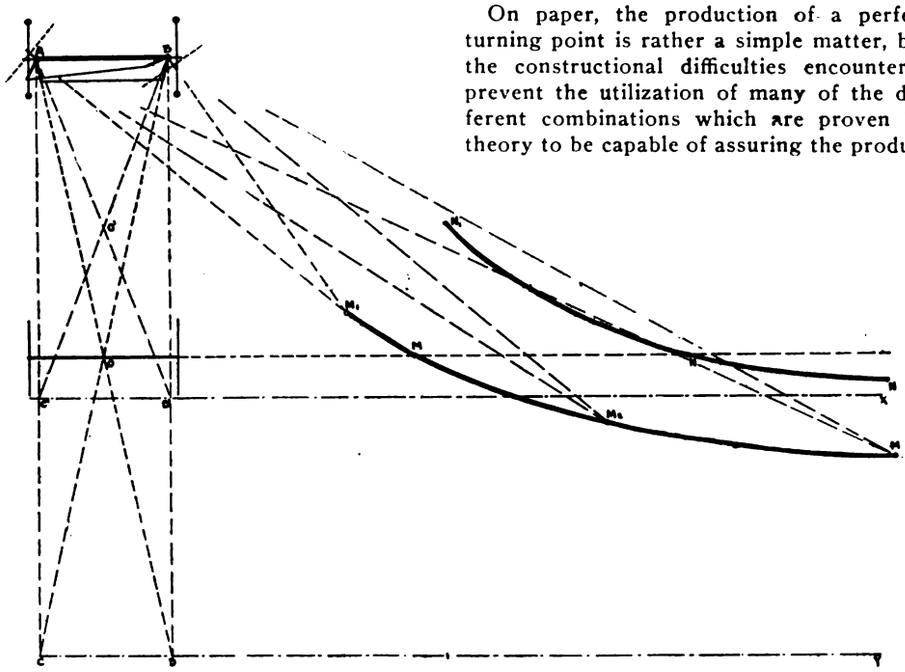
Where a pump is utilized to circulate the cooling water, it is wise to fill the radiator to the top and then turn the engine over several times, so as to insure the water reaching and filling all parts of the system. If the motor is not turned, the pump is an obstruction to the passage of the water into the jackets, which remain partly empty, or fill so slowly as to leave the impression that there is more water in the system than there actually is.

CLAIMS FIRST FOUR-CYLINDER CAR

New Jerseyman Arises and Avows That He Built It in 1898—And Despite Crudity It's Still Going.

The question as to who built the first four-cylinder motor car in the United States always has been a mooted point, and it has been discussed, with unsatisfactory results, on several occasions of late. Within the last week, however, a claimant for that honor has arisen in the person of Fred F. Smith, of Bridgeton, N. J., who became interested in self-propelled vehicles early in their history and built one, which still is in running order and giving a good account of itself.

It was in 1898 that Smith commenced the construction of a two-cylinder car, but when the machine was practically completed he went to Paris, where he attended the Exposition, saw the cars exhibited there, and decided to change his own machine from two cylinders to four. He purchased a four-cylinder motor with a bore and stroke of 3¼ and 3½ inches, respectively, which was installed, driving through a propeller shaft and bevel gears to a jackshaft and thence by side chains to the rear wheels, which were mounted on a solid steel axle.



The steering wheel was on the left side and the control located in the center. The body was purchased from the Columbus Buggy Co., of Columbus, O. Smith's car is not touted as a racing machine by any means, but is said to be entirely capable of traveling under its own power, notwithstanding the fact that it is some fourteen years old.

DETERMINING THE ANGLE OF STEERING KNUCKLES

Little Known Problem of the Steering Gear and the Effect Its Solution May Have on Tire Wear and Skidding—Comparison of American and French Methods of Designing That Reveals the Results Obtained With Both Systems—How They Differ.

Of the very many problems, some simple and others more or less involved, which occupy the time and try the patience of the automobile designer and constructor, probably none is more important than the production of an efficient and reliable steering system—a system strong and rigid throughout, and yet capable of quick movement by the operator, and which will at all times answer to the slightest pressure on the guiding wheel, impart direction to the car, and yet so constructed that the

GRAPHIC PORTRAYAL OF STEERING KNUCKLE ANGLE ERRORS

great pressures which are occasioned by the road wheels encountering obstacles, which tend to cause them to veer from their course, will produce little or no effect on the guiding wheel.

Likewise, such a steering system as this must be so designed that the chance of slideslip and skidding is reduced to a minimum when the car is being turned, and it is in the achievement of this last requirement that many interesting problems arise—problems which have been studied since "horseless carriages" first were evolved from the horse-drawn kind, and which probably will be studied until study ceases to bear fruit. Not that the system in vogue and which, in theory at least, is standard with practically all manufacturers is lacking to the degree where change is essential, but still it is not yet perfect, and until it is perfect improvement naturally will be sought.

A perfect turning point for any vehicle is a point so located that each of the wheels of the vehicle travels in a curvelinear path around this point as a center, and it is this factor that occupies more of the designer's mind that the outside world ever dreams. The conditions for the production of a perfect turning point, then, require that the prolongations of the axis of rotation of all of the four wheels intersect at a common point.

On paper, the production of a perfect turning point is rather a simple matter, but the constructional difficulties encountered prevent the utilization of many of the different combinations which are proven by theory to be capable of assuring the production of a perfect turning point, no matter what may be the steering angle.

The fulfilment of the conditions for obtaining correct steerage on a two-wheeled vehicle, such as a bicycle, or on a three-wheeled one wherein one wheel is used for steering and the other two are mounted on a common axle, embraces the use of no special apparatus, for it is obvious that no matter what may be the relative angle of the steering wheel, the prolongation of its axis of rotation always meets the prolongation of the axis of the other wheels. This is true also of a four-wheel vehicle wherein steering means are provided by pivoting the front axle in the middle, as in a wagon or a carriage, but obviously this method of steering is unsuitable for automobile use, for not only would the operation of such a device be difficult, but the frame of the car would be made unstable and the road shocks would be unduly severe on the whole steering system because of the large turning moment due to the distance of the wheel from the pivot.

The use of a split front axle, with the wheels mounted on rotatable stubs which were linked together so as to travel through corresponding arcs was first suggested and tried fifteen or more years ago by the English designer, Ackermann, but the difficulty was that if the stubs turned through the same arcs the axes were at all times parallel when the wheels were traveling in a curved path, and therefore the prolongations never could meet and the formation of a correct turning point was an impossibility. In other words, each wheel was tending to turn on a center separate from the center of the other wheel, and skidding resulted.

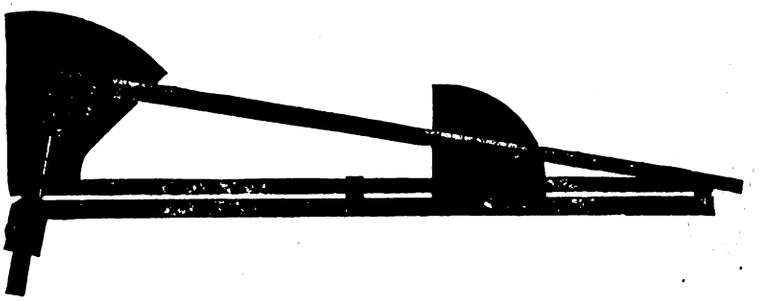
Ackermann's steering axle was improved by Jeantaud, a Frenchman, in a manner which made the application of the device to the modern motor car possible. Jeantaud's improvement was quite simple. Instead of making the angle formed by the intersection of the steering stub and the lever which served to turn it a right angle, as Akermann had done, he made the angle greater than the right angle, so that the connecting link, or tie rod, was shorter than the length of the solid portion of the axle, and as a consequence in turning the inside wheel always turned through a greater arc than the outside wheel. The axes of rotation, therefore, converged and met in a point. The two wheels circled this point as a common center. Jeantaud's method of determining the angle between the pivoted ends of the axle and the levers which serve to turn them is shown in the accompanying diagram. A and B are the pivots around which the movable parts of the axles bearing the wheels rotate; O is the rear axle. A point, O, in the middle of the rear axle is chosen, and from this point lines are drawn to A and B. These lines determine the angles the steering stubs make with the turning levers.

If the wheels are considered as having been turned so that the steering angle is successively 40, 33 and 25 degrees, and the directions of the axes of the steering stubs are produced in each case until they meet, it is found that when the points of intersection of these axes, M_1, M_2, M_3, are joined by a line, this line forms a curve, and the amount of bend in this curve is greatest when the steering angle is greatest, and that the curve tends to straighten out as

Digitized by Google

the steering angle is decreased. A contributor to Omnia has shown that the curve thus formed continually approaches, although it never meets, a straight line; or, putting it mathematically, the curve approaches an asymptote. A glance at the diagram reveals the fact that the curve crosses the line O N, which is the axis of rotation of the rear wheels, in but one point, M. Correct steering is obtained only when the axes of rotation, prolonged, meet in a common point, and therefore, with this method of causing the convergance of the axes of the steering wheels, correct steering is obtained at only one steering angle.

The determination of the location of the asymptote is, according to Omnia, a very simple matter, as well as a matter of some importance, for the location of this line determines the relative error at the different steering angles. If the lines A O and B O be produced their own lengths through O, and the ends there joined so as to form the parallelogram A B C D, the line C D is the asymptote of the curve M_1 M_3, and is located at a considerable distance behind the rear axle. If the location of the asymptote were chosen with regard to its distance from the rear axle and used to determine the angles of the stub ends of the steering knuckles to the levers, many benefits would accrue therefrom, for the point of correct steering could, by properly locating the asymptote, be made at the steering angle most commonly used. Just what difference the location of this line really does make is shown in the diagram. The curve N_1 N_2 is formed when the position of the asymptote is chosen at a point directly behind the rear axle; the parallelogram is therefore foreshortened, forming A B C' D', and the diagonals of this paralellogram determine the angles of the steering knuckles. The angles are found to be greater the nearer the asymptote approaches the rear axle. A comparison of the two curves reveals that the curve M_1 M_3, as the steering angle is decreased, after having passed point M, diverges more and more with relation to the axis of rotation of the rear wheels ON, and that, therefore, the steering error must be relatively greater when the steering angle is small; with the curve N_1 N_2, however, the curve can never diverge to a very great distance relative to O N, due to the proximity of the asymptote to the rear axle. Under ordinary conditions of driving, claims the French writer, when the steering wheel is continually turned through comparatively small arcs in order to avoid bad places in the road or other obstructions, the tendency for the car to skid is very much less when the asymptote is located near the rear axle than is the case when steering knuckle angles are determined by lines drawn to the midpoint of the rear axle.



Where pivotal steering is adhered to, the determination of the angle of the steering knuckles is by an analogous method, the parallelogram, however, instead of being determined by the distance between the pivots and the distance to the asymptote, is determined by the wheel tread and the same distance. The diagonals of this parallelogram determine the angle of the steering knuckles.

Just why there is a marked tendency toward side slip and skidding when the axes of rotation of all the wheels when prolonged do not meet in a common point, easily may be illustrated. If the front truck of a railroad coach which is rounding a curve passes safely over a switch, but for some reason or other the switch is then thrown so that the rear truck passes around the siding which diverges from the main track, it is evident that before many feet are covered "something has got to go," and nine chances out of ten one of the other of the trucks leaves the rails. The same thing occurs with the automobile when the steering angle is such that a proper turning point is impossible; one or the other set of wheels slips or skids, regardless of the nature and condition of the road surface. The importance of the correct angle, therefore is manifest.

Instrument to Determine Chain Lengths.

While it would seem at first thought to be a comparatively simple matter to determine the length of a chain required for the ordinary motor car, in reality it is necessary to resort to a mathematical calculation of no little complexity in order to arrive at the correct figure. It is with a view to eliminating the trouble and the loss of time involved where such work has to be done frequently, that the Diamond Chain & Mfg. Co., of Indianapolis, Ind., has brought out an instrument styled the "Lineometer," the use of which makes it an easy matter to ascertain the length of a chain, either rolled or block type, or of a belt. The diameter of different sized sprockets or pulleys are considered, of course.

The instrument is made in two types—one of paper, suitable for occasional use, and the other of steel throughout. The illustration, which is of the steel instrument, shows the construction. Two sectors are mounted on a slotted bar, which is marked off to correspond with chain pitches. The right-hand sector is movable along the bar and is fitted with a screw clamp for holding in it any desired position, while the left-hand sector is movable vertically. The straight edge above the bar is pivoted at the right-hand end. In working out the length of a chain, the two sectors are adjusted so that the upper edge of the straight-edge cuts the arcs marked on the sectors, which represent the diameter of the sprockets that are to be used; the smaller sprocket will be represented by the arcs on the right-hand sector. The readings on the straight-edge at the points where it cuts the arcs, and on the arcs themselves, are added together, the sum being the length of the chain required in terms of the pitch, and a very simple calculation gives the length in inches. By varying the setting of the instrument, according to the directions furnished, the reading can be made to cover chains of different types and pitches and belts, crossed or straight.

DIAMOND LINEOMETER FOR DETERMINING CHAIN LENGTHS

"Ethylite" Becomes "Butylite" Lamp.

Under a new name, but only slightly changed in external appearance and mechanical construction, the Ethylite alcohol automobile lamp, which made a modest bow about a year ago and apparently held considerable promise, is again offered to the public. This time it is called the Butylite—whether in connection with "Butyl" alcohol or as a phonetic spelling of "Beauty Light" is open to argument. Benjamin N. Levy, the New York agent, when seen at his office at 32 Union Square, stated that silght errors in the construction of the original Ethylite lamps and the difficulty of arranging for proper manufacturing facilities had made their marketing slow—so slow, indeed, that a change of name was finally decided upon as offering better chances of success. The only mechanical change made is in the distance between the opening of the alcohol tube and the incandescent mantle. The lamp is claimed to burn one hour for one cent, throwing a light of 70 candlepower, without reflector, but capable of being dimmed to five candlepower if so desired.

Acid That Injures Leather and Fabric.

The acid in the electrolyte of a storage battery is extremely destructive to leather and fabrics, and also to rubber goods, such as raincoats. The immediate use of clean cold water to wash off the acid is the best thing, while the application of ammonia will neutralize the acid and minimize the discoloring action if the solution gets on the clothes. It is a very disagreeable liquid to splash around, however, and should be treated with a good deal of respect.

ONE TRUCK SURE OF A CLEAR ROAD

"There's a Reason" and It Is Not Easy to Guess It by Looking at the Picture—It's in the Load.

Safe to say, there are very few motor trucks that are employed for business as hazardous as that for which one is used by the Independent Torpedo Co. As the name of the company indicates, its activities are devoted to the manufacture of products that are highly explosive. Consequently, extreme care is necessary in transporting them from place to place. Nitroglycerine, for instance, is one of the substances which is used extensively, and, as everyone who is even remotely acquainted with it knows, it does not require a very great effort to explode it. Sparks or fire are not necessary; to drop a can of the material generally is sufficient to invite immediate "action," and a slight blow has been known to cause disaster.

In casting about for a solution of its transportation problem, which heretofore revolved around a couple of horse-drawn wagons, the Independent Torpedo Co. pinned its faith to the product of the Adams Bros Co., of Findlay, O., and it is a stock Adams truck, equipped with a special body, that is used in the hyper-dangerous business of conveying nitroglycerine from State to State, according to the field of operations of its owners. Only one change from stock equipment was made in the chassis, and that consisted in substituting Swineheart cellular non-skid tires for the plain-tread tires usually supplied with the truck. The body is stock, except that it has been slightly modified to meet the requirements of the work for which it is intended. The regular body is lined with a sheet-metal pan, in which rests a special body divided into a number of compartments, each compartment being of just sufficient size to hold a single can of nitroglycerine. The inner body also is fitted with a pan, to guard against any of the explosive liquid getting into the transmission elements of the truck. The top of the inner body is strengthened and forms a platform on which torpedoes are carried. They are held in place by means of side stakes attached to the outer body.

The full capacity of the truck is 720 quarts of nitroglycerine, though even part of a single quart would prove sufficient to blow the truck and the driver pretty nearly completely out of sight.

ADAMS TRUCK WHICH IS EMPLOYED IN THE HAZARDOUS BUSINESS OF TRANSPORTING NITROGLYCERINE

About Demagnetization of Magnetos.

If the reversal of the current in the armature of a magneto will demagnitize the field and render the apparatus useless, for the time at least, why does not the reversal of the field, or the bucking of a permanent field by a counteracting field, which regularly is done in order to secure regulation on lighting dynamos, cripple the dynamo? is a question that occurs intermittently. The reason is plain: The current operating the bucking field is but a part of the total output of the machine, and the field itself is so wound that when operating under full current strength the strength of its magnetic field is never so great as that of the main field. Consequently, as the bucking field never can be in operation save when the main field is at full strength, total demagnetization of the main field is impossible.

LIQUEFIED GAS FOR AUTOMOBILES

Government Chemist Shows Possibilities of Natural Gas for Internal Combustion Motors—Its Many Uses.

It is by no means beyond the bounds of possibility that the search for a fuel for internal combustion motors, when the price of gasolene rises to a height that will make it practically unattainable, will develop fuels that at present are given little consideration in discussing the fuel of the future. In this connection it is well known that experiments have been made with natural gas stored under moderate pressure and carried on a motor truck in tanks, being fed to the motor through a suitable valve and mixed with air in a simple mixing valve; and there would seem to be a considerable field, for experiment at least, in this direction, for the volumes of natural gas that go to waste are enormous, and the successful use of natural gas for vehicle propulsion might bring about appreciable economies. There is no question as to the cheapness of the gas itself, and the most serious item of expense would be the compressing and tanking. So far as power is concerned, the results obtained from the natural gas are said to be on a par with those obtained from gasolene, so far as can be judged from the operation of stationary engines.

Another step in this direction recently has been taken by Dr. Walter O. Snelling, of Pittsburgh, Pa., who is a consulting chemist attached to the United States Bureau of Mines and the Panama Canal Commission, and who has succeeded in

Digitized by Google

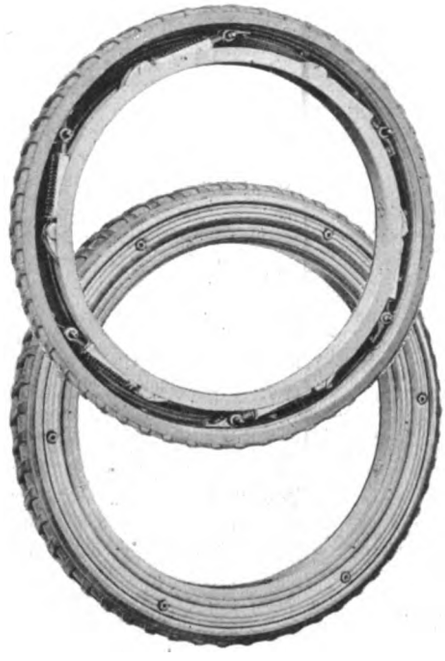
liquefying natural gas by a process which is said to be commercially practicable.

"By the new method of rectifying the condensed portions of natural gas," he says, "it is possible to obtain a liquid gas, which seems quite ideal for the lighting of isolated dwellings, etc. In the liquid form the material exerts a pressure of but 500 pounds per square inch upon the container, and upon release of pressure it expans to 350 times its original volume, and each volume of the expanded gas is equal in heating power to four times its volume of coal gas."

While Dr. Snelling has carried on most of his experiments with liquefied natural gas with a view to its use for illuminating purposes, and is particularly interested in that field of utility, he has made experiments in the running of gas engines of both stationary and automobile types. Apparently there is no obstacle to its use in this way, for the results obtained are said to have been perfectly satisfactory. It is evident, however, that Dr. Snelling is eminently a practical man, for he refrains from dreams of the future and says: "As a good quality of gasolene would be more readily available at most places than would the new liquid gas, I am hardly inclined to believe that it will have a field of usefulness in automobile propulsion at present."

In the matter of the proportion of this gas which must be mixed with air to form an explosive mixture, the new fuel is not particularly elastic; the range is only from 3 per cent. to 7 per cent. Therefore, while the proper feeding of the gas for the purpose of running an engine is not a matter of any great difficulty, its use for motor starting purposes, where the method of procedure would be to force a small quantity of the gas into the cylinders already filled with air, would be of problematic success, because it would be extremely difficult to strike the right proportion. Acetylene, which has an enormously wide explosive range, is remarkably suited to this work.

As an illuminant for use in automoblie headlights, Dr. Snelling states that though the gas burns in an open flame with a fairly bright light, it is inferior to acetylene in this respect, and it is only when burned in a mantle that the best illuminating results are obtained. Experiments are in progress with a view to developing a mantle suitable for motor car work, but no definite conclusions have been reached as yet. Though the gas is natural gas, it is somewhat altered as to its characteristics in the process of liquefaction and the attendant purifying, so that when used with a mantle it is said to have eight times the illuminating power of natural gas and five times that of coal gas.



Rope as Substitute for Starting Crank.

A pull on a rope which has been wrapped several times around the flywheel and "clinched," ofter will start a motor when the crank has been lost or broken.

HERE'S ONE MORE SPRING TIRE

Hails from Kansas City and Cleveland—Employs Vanadium Steel Springs and Fits All Types of Rims.

Among the most recent additions to the already long and ever lengthening list of devices designed as substitutes for the pneumatic tire, is the Ferromatic tire, for the manufacture of which a company has been organized under the style the Ferromatic Tire and Manufacturing Co., of Kansas City, Mo., and Cleveland, O., with a capital of $180,000. The new tire, which differs little from a pneumatic of equal capac-

FERROMATIC SPRING TIRE

ity in size and general appearance, depends for its operation upon a combination of steel springs and rubber, and will be made to fit any standard type of wheel, including those for use with quick detachable rims, clincher rims and some types of demountable rims, without alteration of the wheel itself.

Two steel shells concentrically disposed, with steel springs interposed, form the tire, the outer shell having a peripheral covering of rubber, which forms the tread, and the inner shell taking the place of the ordinary tire channel. The rubber tread may be of a non-skid type, or of any desired form. Between the two steel members are placed vanadium steel springs, of helical form, varying in number from five to eight, according to the size of the tire, one end of each spring being connected to the inner shell and the other to the outer shell, so that the tendency of the car's weight to bring the shells together at the bottom is resisted by the springs. The weight of the Ferromatic tire is said to be not very much greater than that of a pneumatic tire of similar capacity.

Hartford Demonstrates Starting System.

By way of demonstrating the efficiency of the Hartford lighting and engine starting system, which is manufactured by the Hartford Suspension Co., Jersey City, N. J., famed as the producers of Truffault-Hartford shock absorbers, E. V. Hartford, who is the inventor of the devices, personally conducted a demonstration of the system in the building of the United States Motor Co., on 61st street, New York City, on Tuesday morning, 16th inst. Though the system was exhibited at the automobile shows both in New York and Chicago, this was the first time that it had been seen in actual operation on a car. The car on which the system was mounted was a six-cylinder 90-horsepower Thomas, and despite the diminutive size of the starter it "cranked" the big engine time and again without the slightest hesitation. In its entirety the system embraces a generator and a motor, which are separate, an automatic cut-out to disconnect the generator from the battery when the motor is stopped, and a storage battery.

The motor, which is barely more than 5 x 8 inches over all, is connected to the engine by means of a combination spur and worm gearing, and because of the great reduction obtained operates at exceptionally high speed, fluctuations in the load caused by the pistons passing compression centers being absorbed with the aid of a miniature flywheel mounted on an extension of the armature shaft. The starter may be connected to the engine either through the timing gears or through the transmission. The generator for use in charging the storage battery is separate from the starting motor and is operated from the pump shaft by means of a "silent" chain or a belt, whichever may be most convenient. After the demonstration, which was for the particular benefit of newspaper men and the officials of the U. S. Motor Co., several of whom, including Horace De Lisser and Alfred Reeves, were present, Hartford led his audience to Rector's, where a luncheon was served and several addresses of an informal nature made.

If Water Pump Should Be Disabled.

The breaking of a pump driving shaft or coupling, and consequent disablement of the pump, need not of necessity cause dismay, provided care is used. If it is possible, remove the members of the pump which prevent the free flow of the water through it. If this is not possible, disconnect the pump altogether and place a straight piece of hose between the radiator and the water jacket manifold. If the radiator is filled to the top, thermosiphonic circulation is set up, but the circulation is not nearly so fast as with the pump, so that the spark should be fully advanced and due caution exercised so that the motor will not overheat.

FOLLOWING THE LINE OF LEAST RESISTANCE

Electricity Has an Even Chance with Gasolene in the Truck of the Future, Contends the Designing Engineer—Independently Driven Wheels Likely to be a Factor in Attaining Results—Gasolene Trucks Compared with Locomotives from the Point of View of Economical Operation.

"So that reporter fellow's been after you, too, has he?" said the Designing Engineer to his second assistant, as he endeavored to make room for his hat and coat on the office "tree."

"Looks that way," replied the second assistant, grinning. "I didn't know it at the time, though; I got talking to that fellow from downstairs, and I suppose he passed it on to the newspaper chap. Did I tread on the toes of any of your pet ideas?"

"Not a bit of it," assured the D. E. "You are looking at it the wrong way. The things I expressed were not in the nature of pet ideas or hobbies, or anything of the sort. It's just my opinion, from what I have seen of the motor truck business, that machines will be developed, as I said, along the lines of the machines now in use. Why not? It's along the lines of least resistance, and the progress of a great big industry isn't like the progress of an individual experimenting in a laboratory 'all alone by himself.' The individual will work along the lines that look best to him, until he sees something that appeals to him as being a whole lot better, and then he can chuck the old stuff into the scrap pile and make a brand-new start in the new direction. But it's hard to do anything like that when the whole world, more or less, has to be brought to a stop, turned round and started on another tack. You can convince some of the people, but you can't convince them all—not at once, anyway—and those who are unconvinced will do their best to prevent the making of more converts. Just imagine what a job it would be to get all the truck makers to abandon even part of their present plans and start doing things in a totally different way!"

"But you're not talking engineering at all," said the second assistant; "that's rank commercialism."

"Of course it is," assented the D. E. "I didn't say it was anything else. I said clearly that I was giving my opinion as to what actually would happen—not what I think ought to happen, or what I would like to have happen. Development has been proceeding on certain lines, and I believe that makers will stick to those lines for some time to come, rather than spend a whole lot of money experimenting in other directions."

"But that means getting into a rut," objected the second assistant.

"Nothing of the sort. Anything that is really good will be taken good care of. But you can't expect a whole industry to drop everything and turn to new ways all at once, no matter how good someone may think—or even prove—such ways to be. Someone has to do the developing first, put the machine to the test and prove its worth by years of service. And if it is a success, one of the first indications will be that the rest of the industry will immediately get to work to improve what already is in common use, so that there will be less margin for odious comparisons."

"That's about the way some of the poppet valve motor people have been doing since the sleeve valve began to get in its fine work," suggested the second assistant.

"Exactly. And you can see for yourself how poppet valves have improved of late. There's nothing like competition to bring out improvements."

"Don't you think, though, that the electric vehicle will have some sort of a place in the truck procession of the future?"

"Well," said the D. E., thoughtfully, "that's a thing that has been running in my mind a good deal since that newspaper fellow was up here and turned me inside out on the subject of gasolene trucks. Of course, there is no question about the electric motor itself; that's a thing that has been in use in so many different forms that it doesn't figure much in the line of trouble maker. Of course, there is room for improvement; you can say that about anything that's made—I don't care what it is. But it seems to me improvements are more likely to be made in the designing of vehicle motors of special forms, so that the drive can be more direct than usually is the case; for instance, a slow-speed motor built into a wheel, so that the hub forms the armature and the fields rotate with the wheel. That would do away with all kinds of gearing."

"Why, there's nothing new about that idea," said the second assistant. "I have seen a machine built about like that right here in New York, and there are a good many of them in use abroad."

"Sure—I know it. I'm not claiming to be the originator of anything. I'm simply following the same old idea of developing what we already have, which, it seems to me, is the most natural and likely way we can make progress. But even the man who builds motors of that kind acknowledges that they are not by any means perfect, for when it comes to a slow, heavy pull the rotative speed is so very low that an excessive amount of current is consumed without an adequate return in the shape of work done, and even on level ground the draw on the battery is pretty heavy, as compared with high-speed motors. But you can't say that that type of motor will not be developed to a point where it will operate economically and pull well running slowly; and when it can be made to do that it will be a mighty fine thing, without any doubt at all. In fact, in spite of the hard row they have had to hoe and the set-backs they have had, to say nothing of the shyness of the public in taking up anything that is radically different from most other things of the same class in use, I'm inclined to think there is a great future for the truck with each wheel independently driven, whether it drives through two wheels or four."

"Then it looks as though there might be a pitched battle for supremacy between electricity and gasolene—or what ever comes after it," suggested the assistant.

"Oh, there always will be lots of room for both, and there always will be people who will like one and not the other, as long as both are capable of doing the work required. But I do think the time will come when electric trucks will be used for long-haul work, which they can't do now; that is, speaking of electrics as a class. It's the old story—the limitation of a battery charge. But batteries are improving at a great rate, and it is possible to get much greater radius from a given weight of battery than was possible a few years ago. Suppose a battery is developed that will run a truck as fast as it is safe to run it and keep it going for a couple of hundred miles without recharging—a battery combining the good features of the best batteries now on the market and leaving out most of the trouble—can't you see what a tremendous boost the electric vehicle would get?"

"Yes," admitted the assistant. "But how are you going to do that? If you use a battery that's light, it's bulky, and if you use a battery that's compact, it's heavy, and a battery that would keep a heavy load running anything like a couple of hundred miles would be a load in itself."

"You will insist on forgetting," said the D. E., a little testily, "that I'm not pretending to say how these things are to be done. It's merely my opinion that the logical development lies in that direction."

"That's right," admitted the assistant; "I forgot. But what do you think," he added, "of the remarks I made to the man from downstairs? Doesn't it seem to you that there's a good deal in the idea of injecting

Digitized by Google

water with the gasolene, and don't you think the carburetter is bound to give way, sooner or later, to a fuel injection system?"

The D. E. scratched his head.

"Well," he replied, "what I really think about the water business is that it is all right in itself, except that it adds complication, and the use of high compression makes finer and more expensive work necessary, and the driver has another set of apparatus to look after. But I don't think that matters much in motor car work, because I believe that the expense of fuel will be likely to stimulate the production of a cheaper kind of hydrocarbon rather than a more expensive and complicated kind of motor; and that fits in with your remark that when your pet ideas are developed we won't be using gasolene. As for fuel injection, I agree with you that it's bound to come, though I am inclined to believe it will be handled by keeping the fuel under constant pressure and admitting it by valves that can be regulated as to opening, or time, or perhaps both.

"I think there will be a great deal of compromising in evolving the motor car or motor truck of the future—especially the truck, which I have had in mind right along rather than the pleasure car. It will be something like the evolution of the steam locomotive, which now is pretty nearly as good as it ever will be, for probably it will be displaced by electric or internal combustion locomotives before it can be developed a great deal more. Take locomotives as a class: They are not the most economical steam engines that can be produced; they could be made more economical of fuel by adding complications. But on the other hand, they are not the simplest steam engines that can be made to do the work; they could be more simple, but not without a loss of efficiency. The locomotive is a compromise between maximum thermal efficiency with a lot of complication, and minimum complication with low thermal efficiency. In other words, it is so worked out that its entire cost from the cradle to to grave—rather, from the drafting board to the scrap-heap—including operation and repairs, will be as small as possible with relation to its earning capacity. It is the same with a motor truck. Maybe it will be possible to build a truck that will be a remarkable machine so far as its mechanical and thermal efficiency are concerned; but if the cost of construction runs so high that it balances the extra earning capacity, what would be the use? The user of the machine wouldn't be a bit ahead. In fact, a bad accident might put him a lot behind."

"Not unless he was idiotic enough not to insure the machine," interjected the assistant.

"Right; I forgot the insurance business. But that brings in another item—the higher cost of the insurance on a very expensive machine, which would help to bring up the expense of maintenance. My point is that the truck of the future ought to be a machine that will do its work with reasonable economy, but will be of extreme simplicity mechanically, comparatively inexpensive to manufacture and very unlikely to go wrong through the failure of any of its very few parts to operate properly. And it's a whole lot simpler to change the fuel to something cheaper than gasolene, and build the engine to suit, than to build a more expensive motor and then add complications as well, and still use the more expensive fuel. It's adding two evils to cure one.

"There's something else that has to be considered when you are talking about improvements in motor trucks," continued the D. E. "In forty or fifty years it is pretty safe to assume that roads and streets will be something very different from what they are to-day. Long before that, owners of motor trucks will have become very tired of having their machines banged to pieces on the abominable roads we have now, and manufacturers will be tired of trying to build trucks strong enough to stand the racking such roads give them; all so that money will not have to be spent on the highways. And long before that time the users and the manufacturers of motor vehicles of various kinds will be so numerous and so strong that they will be in a position to stand up and say what they want, and see that conditions are made what they ought to be. So trucks will have to be built to stand only occasional overstraining—not a continual performance, as at present. And that will to a very large extent remove the necessity for a governor, for there is no reason in the world why a truck should not be run just as fast as traffic and its own power will permit, if the roads are approximately perfect. On a long haul it would be folly to set a governor so that the machine would be held down to, say, twelve or fifteen miles an hour, with a long stretch of straight, smooth, sandpapered road ahead. It would mean throwing away time, which is money. Governors are the thing for the present, for there are practically no roads where it is safe to run a truck at any great speed; but roads are now built for horse speeds, and you might drive over a road with horses at their normal speed and take away the idea that the surface is very fine indeed, and then go over it with a motor car at its normal speed and think it an entirely different sort of road. And it really would be, for what is a good road for a horsed vehicle may be a bad one for the faster-moving motor vehicle."

"H'm," said the second assistant, thoughtfully, for he rode a motorcycle and was painfully familiar with a great many road surfaces. "There's a great deal in what you say about the roads."

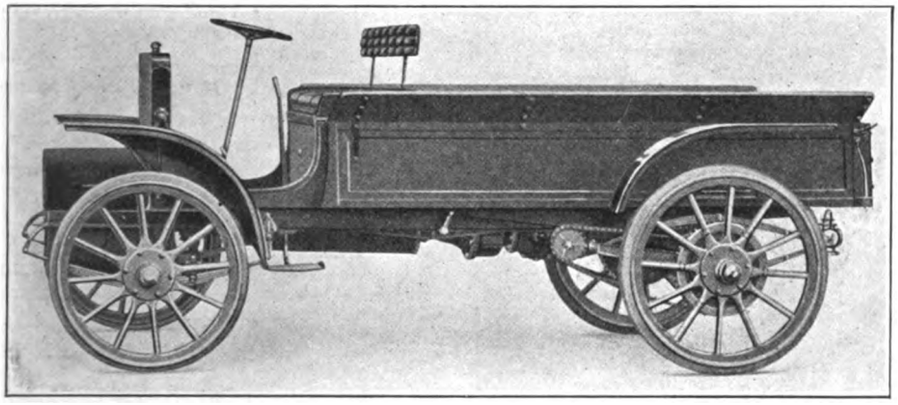
"There certainly is; and if you want to get an idea of the difference in hauling a load over a good or bad road you ought to ride for awhile on an electric truck fitted with a volt-ammeter, and just note the difference in current consumption on different kinds of surfaces. It is surprising. You don't notice it much on a gas truck, because there's nothing much to indicate the differenve except the bumping and jouncing.

"And there's another thing that I think will be worked out in the not far-distant future. There is a very great difference in the amount of power absorbed by different solid rubber tires. The shape of the tire, its size and the composition of the rubber employed in its manufacture all have their effect in either wasting or economizing power, and naturally it's in the electric truck, with its meter, that this difference shows up, though, of course, it exists on any car, whether there is anything to show it or not. I have seen a truck run through a series of tests with tires of different kinds—all solids—to see what variation there was in current consumption. With absolutely no difference in loads or roads, and practically none in weather conditions, and using the same stretches of road all the time, there was found to be a variation of 20 per cent. in the power to drive the truck with the most economical and the least economical tires on the wheels. These figures were not extremes, but the average of a number of careful tests. Now, it seems to me reasonable to expect that tire makers some day will pay a good deal more attention to this matter than they do at present, though I know some of them already have gone pretty deeply into the matter."

"Don't you think that by the time the roads are sandpapered, and all that sort of thing, trucks will be carrying much heavier pay loads than they are now?"

"Undoubtedly. That's only reasonable. But then up comes the old question of the limit of endurance of rubber. You know rubber can be broken down, structurally, and made useless by excessive compression, just as it can be broken by excessive stretching or by cutting or tearing, so that it cannot be restored to its original condition. So, unless something better than rubber turns up, I don't see how the loads can increase very much. I do think, however, that there will be a great deal of development along the line of trailers or the semi-trailers that a number of manufacturers now are using. With these arrangements you can carry your power plant on rubber tires and the load partly or altogether on steel tires, with a corresponding reduction in tire expense, both in first cost and in up-keep. The semi-trailer plan seems to be coming more into favor all the time, and more makers are adapting their outfits to use it."

At this juncture the office boy ventured to call attention to the fact that there was a man waiting to see "the boss," and the D. E. and his assistant turned to see "that newspaper chap" scribbling away for dear life at the office boy's desk.



"Thanks," he said, edging toward the door. "I just came up to ask a few questions, but as you didn't pay any attention to me I made use of shorthand. I guess I got it all." And with a grin he departed.

ANOTHER WAGON MAKER SEES LIGHT

And Seeing It, He Adds Motor Trucks to His Productions—Characteristics of the Geneva.

It is one of the signs of the times that manufacturers who long have been identified with the manufacture of horse-drawn vehicles are in many instances keenly alive to the fact that the motor vehicle for commercial work is nothing short of inevitable, and, rather than relinquish any part of their reputation for progressiveness, are taking up the motor car business. One such concern is the Geneva Wagon Co., of Geneva, N. Y., which just has entered the commercial motor car field with a light delivery wagon of particularly neat design. This Geneva wagon is built with two standard types of body—one an open express and the other a closed panel body. Only one type of chassis is built, having a two-cylinder motor with opposed cylinders, located under a short hood forward of the dashboard. Perhaps the most conspicuous feature of the car is the extreme accessibility of the motor. When the hood is removed the whole top and forward end of the motor are exposed and are easily reached by the operator from the front, between the wheels. Carburetter, magneto, force-feed lubricator, pump, valve mechanism and piping are all readily reached, without the necessity of leaning over or ducking under anything.

GENEVA DELIVERY WAGON WHICH EMPLOYS HORIZONTAL OPPOSED MOTOR

The motor is rated at 20 horsepower, having cylinders measuring 5⅛ x 4½ inches, and ignition is effected by means of a high-tension magneto mounted on the top of the motor crankcase, in a most accessible position. The cooling water is circulated by a gear pump through a radiator built up of vertical tubes, which forms the dashboard of the car and is thus exposed to air currents and at the same time is out of the way of accidental injury and does not interfere in any way with access to the motor. Control of the motor speed is effected through a throttle lever mounted in the usual position on the top of the steering wheel. The carburetter is a Schebler and is connected to the intake manifold at a point a little to the right of the middle.

Drive from the motor to the rear wheels is through a multiple-disk clutch, a two-speed planetary change speed gear and thence by propeller shaft to a jack shaft, which carries the differential and the sprockets, from which the rear wheels are driven by chains. The framing is of wood, double trussed, and is mounted on semi-elliptic springs in front and full elliptics in the rear; the rear springs are not required to take the driving thrust, substantial radius rods being provided for this purpose. Larger wheels are used in the rear than in the front, the diameter being 36 inches and 34 inches respectively, and the same holds good of the solid tires, which are 2 inches in front and 2½ inches in the rear. The wheelbase is 96 inches and the tread standard, 56 inches. Brakes are of the internal expanding type. Steering gear is irreversible and is controlled by a wheel mounted on a column that is slightly inclined. Both axles are of 1½-inch solid steel, and the wheels run on ball bearings. Ten gallons of gasolene can be carried in the fuel tank, which is placed under the driver's seat.

The open express body, designed as Type B and shown in the accompanying illustration, is 6 feet 6 inches long behind the seat and has a width of 3 feet 7 inches, while the full-panel body is of the same width but is 6 inches shorter, making its length 6 feet. With the open body the vehicle weighs 2,100 pounds, and with the full panel type 2,300 pounds. As its regular equipment, the wagon is supplied with two oil side lights, an oil tail light, a horn and a set of tools.

Armored Cable for Lighting Systems.

Flexible steel armored cable, commonly known as "BX," makes a very satisfactory and very serviceable connection for use with electric lighting apparatus. The wire, which may be had in all of the commonly used sizes, is well protected from mechanical injury and from the weather by the covering, and still is very pliable.

IMPROVEMENT IN THE PEERLESS LINE

All of a Minor Nature, but Making for a More Satisfactory Whole—Priming Pump the Only Novelty.

Following the custom inaugurated several years ago and adhered to ever since, the Peerless Motor Car Co., of Cleveland, O., is among the first formally to place before the motoring public the product of its factories—a line of cars, mounted on five chassis, which is just a step in advance of the line which it supersedes, and which at the present time marks the ultimate of perfection attainable in the eyes of its producers.

Consistent with Peerless policy, considerable attention has been devoted to little things, though none of the big things has been overlooked in the process, and the new cars exhibit no essential changes in construction beyond a slight rearrangement of some of the engine components and accessories. Thus, for instance, the fan now is driven by a built-up V-shaped belt instead of gears, and the lighting dynamo, which forms part of the Gray & Davis outfit, is driven from an extension of the fan pulley spindle instead of from an extension of the pumpshaft. Carburation has been made more efficient by the adoption of a new carburetter with a damper throttle instead of a piston throttle, and adjustments for both main and auxiliary air are made from the dash. Another carburetter refinement lies in the adoption of a new type of T-shaped intake manifold instead of the straight-through manifold which was used heretofore. The exhaust manifold also has been changed to correspond in shape to the intake manifold, the object being to permit of freer exhaust and eliminate back pressure.

The ignition system has been changed, and now is formed of a Bosch dual magneto and a single set of plugs, instead of the two independent systems which have been used in the past; a built-up high-tension distribution bar replaces the vulcanizer bar used heretofore and permits of neater wiring, with decreased liability to short circuits and wrong attachments of the terminals. Except for these changes, the five motors remain the same, the cylinders in each case being of the T-head type cast in pairs. The bores and strokes of the motors are as follows: "24-four, 4 x 4⅝; "40-four," 5 x 5½; "38-six," 4 x 4½; "48-six," 4½ x 6; "60-six," 5 x 7. A clever priming device has been added and is in the form of a small pump, which is housed in the chassis frame and operated by means of a lever extending through the frame below the radiator. To prime the motor it is merely necessary to turn a small dash lever, which connects the pump with the carburetter, when a few strokes of the pump handle suffices to inject a quantity of gasolene vapor and air

Digitized by Google

directly into the intake manifold to facilitate starting. The transmission elements remain unchanged, and in each case embrace the Peerless cork-insert internal expanding clutch, four-speed change gear mechanism and arched full-floated rear axles. The brakes are internal expanding and external contracting, and are located on the rear wheels.

Body changes are few and embrace slight alterations calculated to increase the comfort of occupants of the cars and further accessibility. Domed electric side lights let into the dash have been adopted, and the windshield stays now are turned backward instead of forward, two features which go far toward increasing the already pleasing exterior appearance of the cars. Spare tires are carried on the running board as heretofore, but a depression has been provided, so that they set slightly lower and are more firmly held. Also, in order to increase the straight-line effect and permit a smoothly folded top that lies low, a new type of toggle rest has been adopted which holds the top firmly without danger of abrasion by chafing.

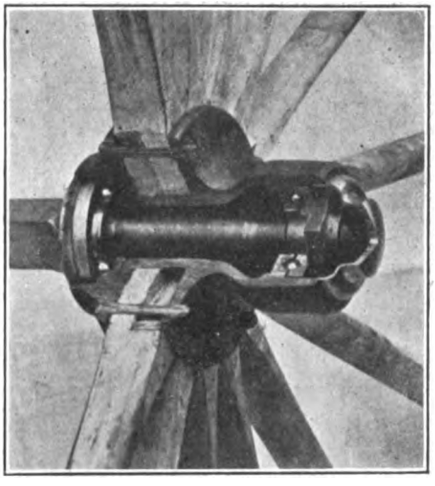
Taking Care of Kerosene's Added Heat.

When adapting a gasolene motor to the use of kerosene by means of a kerosene carburetter or gas producer, it is well to remember that unless some provision is make for additional cooling the motor will run hotter on kerosene fuel than on gasolene. If the piston should be rather a tight fit, this increased heat might possible cause binding, and in aggravated cases seizure. A larger pump should be supplied or the speed of the pump increased to prevent the rise in temperature. It is common practice where a motor is designed for use with either fuel to make the diameter of the piston .02 of an inch less than that of a motor of the same size designed for use solely with gasolene.

Copperplating to Stop a Leak.

Most carburetters of standard design are provided with a "butterfly" throttle valve. There are some, however, which have the "barrel" type of valve, and the constant movement of the throttle as the car is accelerated and retarded causes wear, which results in leakage of air around the barrel and consequent irregular running. About the best method of putting a carburetter so worn in perfect condition is to copperplate the barrel, depositing just enough metal to make the barrel fit tight.

Soft Solder in Place of Washer.



When the small rubber washer located in the valve cap, which serves to check the escape of air from the tire in case the check valve leaks slightly, has become worn out, a few drops of soft solder introduced into the cap will serve the same purpose, and moreover be more durable. The cap should be set down with a pair of pliers for the first time, so that the seat will embed itself in the soft metal.

CLAIMS A "FRICTIONLESS" BEARING

"Suspension Effect" Obtained by "Deflecting Line of Pressure"—Test With Rubber Balls to Prove Assertions!

Though the ordinary type of ball or roller bearing is to all intents and purposes frictionless, the fact remains that there is very slight friction produced, even though it is so slight as to be practically negligible. It has been the purpose of the Suspension Roller Bearing Co., Sandusky, O., however, to eliminate even this minute amount of friction, and to accomplish the result an unusual method of construction has been adopted, which, it is claimed, not only permits an absolutely frictionless annular bearing, but one which may be used to absorb thrust as well.

The bearings are styled the Boyer "suspension" bearings for their inventor, E. A. Boyer, who is the secretary-treasurer of the company which is exploiting them, and the peculiar method of construction is illustrated by the accompanying picture, from which it may be seen that the races, instead of being arranged concentrically, as is usual, are arranged side by side. In the ordinary type of annular bearings, not all the balls or rollers, as the case may be, carry an equal part of the load at all times. With the Boyer "suspension" bearing, however, it is claimed this difficulty is overcome by reason of the construction, which, it is explained by the inventor in his literature, "deflects the line of pressure of the load from the usual perpendicular or horizontal to that of an incline, thus throwing the usual line of the axis of the rotation of the ball from the right angle to the usual line of pressure, to that of an acute angle, thus causing the pressure to fall upon the side of the ball instead of the top or center, resulting in a suspension effect, with the load hanging on or suspended from the balls."

BOYER "SUSPENSION" BEARINGS

Not the least of the claims which are made for the bearings, which may be had in either ball or roller type, is that the weight is equally distributed over all the balls or rollers at the same time; as a matter of fact, it is stated that the bearings "still will perform properly should half the balls be removed entirely, for even then there would be twice as many bearing balls as are at one time performing in other bearings." It is further claimed that, by reason of the true rolling motion which is obtained, friction is absolutely eliminated. To such an extent is it eliminated that "but little oil is advised," and then only sufficient to prevent rust.

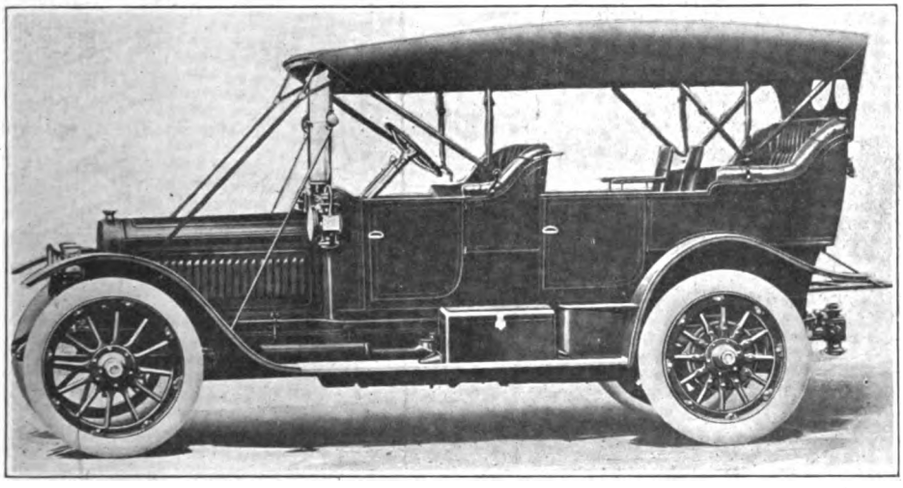
In order to demonstrate that because the load is equally distributed one defective ball or roller will not fracture, it is stated in the literature of the company "that rubber balls and rollers have been placed between the steel balls and rollers in the bearings, and they run as well as when all are steel balls or rollers." "This rubber test," it is summarized, "also proves that we have a frictionless bearing, as the rubber will not slide."

The Economy of Motor Fire Apparatus.

While it is unlikely that any progressive municipality would refuse to avail itself of the superior advantages of motor-propelled fire-fighting apparatus even if the cost of maintenance and operation were greater than that of horse-drawn apparatus, it is none the less gratifying that the cost figures out in a way that makes the older method look like an expensive luxury. Though it is generally known that these costs are so low as in many cases to appear almost ridiculous, the exact data are not often made public, which adds interest to the figures which represent the expense of maintaining the three motor fire engines in use in Roanoke, Va., for the five months ending March 1 last.

Gasolene and lubricating oil for the five months for the three machines cost $51.93 and minor repairs came to $34.40, a total of $86.33. The cost of maintenance for the six horses displaced by the motors would have been $450 for the same period, so the saving effected amounted to $363.67. To put it in another way, the horses would have cost more than five times as much as the motor apparatus, and these figures do not take into account repairs to horse-drawn apparatus.

"Acid Grounds" in Electric Vehicles.



Very often a ground in an electric vehicle, particularly in the case of a large truck, is caused by the slopping of electrolyte, the moisture forming a path for the leakage of a very small amount of current. This is called an "acid ground" and is of no serious importance, and, in fact, often is very difficult to prevent. It cannot be traced to any particular place, and this fact, together with the small amount of current involved, is sufficient ordinarily to indicate what it is.

LOZIER EMBRACES CENTRAL CONTROL

Which Means Left-Hand Steering Also—Triple Ignition Another of the New Features of Latest Models.

Having "felt out" the market with reference to the demand for a left-hand steering wheel, with centrally located control levers, the "feeling" being done with the aid of a closed car of the Berline type, which was announced late last fall, the Lozier Motor Co., of Detroit, Mich., figuratively speaking, has burned its bridges behind it and hereafter all six-cylinder cars at least which bear the Lozier name-plate will be of that order. Which change, together with the adoption of a new oiling system and a new ignition system, constitute the principal difference between the latest crop of six-cylinder Lozier cars, which are designated simply as Type 72, and their immediate predecessors. As heretofore, but two chassis will be produced—the new "six," which rates at 51 horsepower, and the "four," which remains substantially in its original form and rates at 46 horsepower. The prices remain unchanged, the smaller car listing at $4,600 and the larger one at $5,100, either price applying to any of five touring or roadster body styles.

LEFT HAND DRIVE LOZIER "RIVERSIDE" TOURING CAR

Though the new six-clinder motor is a duplicate of its prototype as regards bore and stroke, which are 4⅝ inches and 5½ inches respectively, it is practically a new motor throughout, the location of the steering wheel at the left side and the incorporation of the new oiling system necessitating several material alterations in design. The cylinders still are of the T-head type, which construction long has been a feature of Lozier cars, and are cast in pairs. In order to allow more room for the steering gear, however, the intake and exhaust manifolds have been reversed, as have the water pump and magneto. Coincident with these alterations, the valves and ports have undergone a general enlargement, the result being that though the engine is nominally rated at but 51 horsepower, the actual development on a brake test is in the neighborhood of 80.

Other minor refinements in engine design also have been made, such, for instance, as the incorporation of larger bearings in some parts and a general strengthening throughout. The most noteworthy change which has been made is in the oiling system, which has been altered with the intent not only to provide more efficient lubrication and greater economy, but also positively to eliminate the smoke nuisance, which constitutes a problem of no mean proportions. To this end the variable trough system, which has been used with conspicuous success in Knight engines, has been adopted.

Briefly, the system embraces a number of small troughs, one under each connecting rod big-end bearing, which are mounted on a longitudinal rod running the length of the crankcase. By means of suitable linkage, the rod is connected to the throttle lever in such a manner that as the throttle is opened the troughs are tipped upward, permitting the scoops on the connecting rods to dip deeper into the oil. The oil is placed in a reservoir in the crankcase, whence it is pumped into the troughs after first having passed through a screen. Thus there is always clean oil in the troughs for the scoops to dip into. The inside of the cylinders and the minor bearings are lubricated by splash, which system has been found to be entirely efficient.

As a direct outgrowth of the manufacturer's racing experience, the adoption of triple ignition in place of double ignition is expected to prove of as great benefit for ordinary touring in making available the maximum possible power as it has in racing. As heretofore, a Bosch magneto serves as the source of high-tension current and feeds two sets of plugs simultaneously, one set being located over the intake vales and the other over the exhaust valves. The magneto, however, is of the dual type, and in conjunction with a dry battery of three cells, provides a second and independent source of ignition. This second source of ignition is really a third system, however, inasmuch as either set of plugs may be used alone with the magneto, or they may be used together; only one set of plugs operates through the battery and dash transformer.

Another change which has been made, though it is largely in the nature of a refinement of detail, lies in the adoption of a Rayfield carburetter. The new device provides the greatest average carburetter efficiency over the complete range of engine speeds, and may be adjusted for varying climatic conditions, if such changes become necessary, by means of a lever on the dash, which controls the amount of gasolene in the mixture.

As regards the remainder of the car, no changes of a radical nature have been made, other than that wheel-rim sizes have been slightly increased to accommodate the over-size tire. Power is transmitted to full-floating rear axles through the intermediary of a multiple-disk clutch and the four-speed change-gear mechanism, with direct drive on third speed, is the same, except that the component parts have been slightly altered in position to accommodate the change to central control. The wheelbase is 131 inches and the springs are semi-elliptic in front and three-quarter platform in rear.

To the three styles of touring body which last year were included in the line—the Briarcliff, the Lakewood and the Riverside—there have been added three more bodies, making six in all. The new cars, which list with complete equipment, including demountable rims, lamps, tools, tire repair kit and jack, robe and footrails and tire irons, are the Knickerbocker, which is a closed car of the Berline type; the Meadowbrook roadster, which accommodates three passengers, one of them on a seat on the running board, and the Larchmont, which is a five-passenger touring car of conventional form.

Differential Gear Dates Back to 1826.

The differential gear which permits the driving wheels of a motor car to rotate at relatively different speeds has become so closely associated with the self-propelled vehicle that it is rarely thought of in connection with other types of mechanism. As a matter of fact, however, the differential gear is much older than the automobile, having been patented in England in 1826 by Henry Houldsworth, who devised it as an improvement in spinning machinery, its function being the maintenance of a uniform tension on the threads as they were wound on the bobbins. Apparently the first application to a self-propelled vehicle was made in 1862, when a steam car, designed by D. K. Clark and built by Carrott, Marshall & Co., of Leeds, was shown at the London Exhibition, where it attracted no small amount of attention.

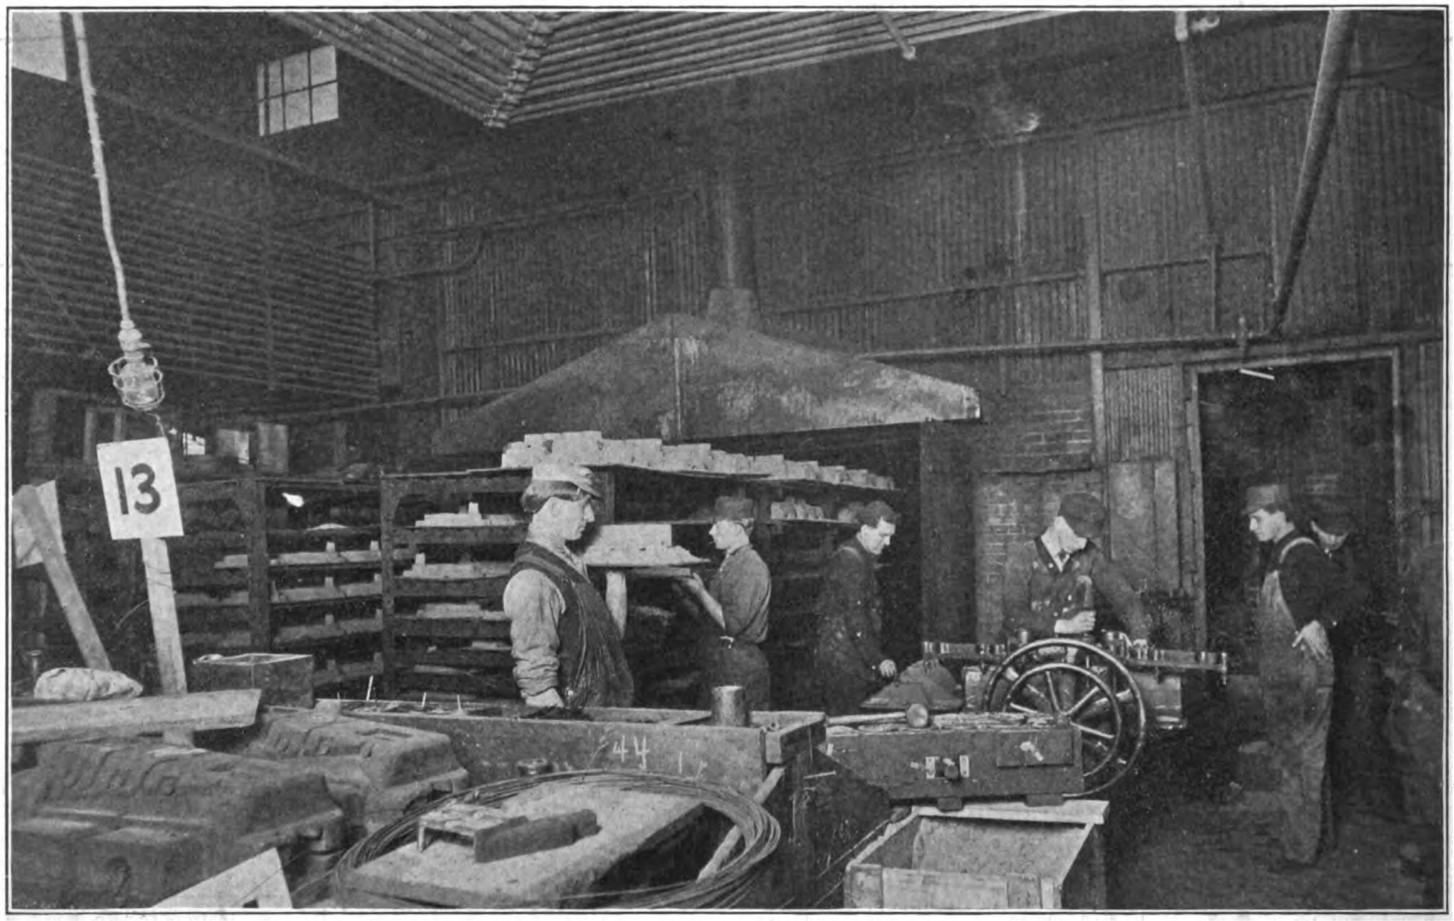
MAKING THE CYLINDERS LIKE NEW

Simple Method of Fitting Liners That Serve to Overcome Scoring and Wear —The Operation Made Plain.

Neither scoring nor uneven wear in cylinders are conditions that are rare, and in not a few cases loss of power and jerky running of the engine may be traced directly to either one of these causes. Fortunately, however, very slight scoring, or the wearing of the cylinders very slightly oval often may be corrected by the simple expedient of placing a small quantity of graphite in the lubricating oil. The graphite must be exceptionally finely ground, though, or it may not serve its purpose, which is to fill up the interstices or to round out the slightly oval spots. Occasionally when the scoring is very deep or the cylinders have become decidedly oval, such measures will not suffice, and it then becomes necessary either to fit new pistons, after having bored out the cylinders, or to fit the cylinders with liners or sleeves.

The latter operation probably is the cheaper of the two, and despite its apparent difficulty, is comparatively simple. Obviously, the pistons should first receive attention and should be trued up in a lathe to the size of the liner which it is proposed to insert in the cylinders. The cylinders should then be bored out to from 13/64ths to 15/64ths of an inch larger than the finished size of the pistons. The liners should be turned in a lathe from close-grained sleeve castings and finished outside .003 of an inch larger than the diameter of the rebored cylinders. They should also be turned with a slight taper at the lower end. The cylinders should then be expanded by placing them in boiling water and allowing them to remain until they are thoroughly heated. It will then be possible to slip the liners in place quite easily after they have first been smeared all over with a solution of sal-ammoniac and water. There will be no necessity for pinning the liners, for, having been shrunk in place, it will be impossible to remove them without breaking the cylinder castings.



Indirect Illumination for Hupp Factory.

Indirect illumination systems, in which the light is first thrown upward and then reflected down, the lamps being concealed, are not uncommon, but it would appear that the Hupp Motor Car Co., of Detroit, is the first to apply the principle to the illumination of an automobile factory. In the new shops of this company the use of individual electric lamps has been eliminated, except in a few cases where concentrated light is required, by the installation of reflectors which hide the lamps from view but project the light upward and then downward in a soft, diffused glow, that not only is effective and lacking in sharp shadows, but avoids the annoyance due to the dazzling effect of naked lamps. The same principle has been adopted in the offices and stock rooms, supplemented in the latter case by occasional extension lamps where necessary.

Why Lubricating Oil Should Be Strained.

Although it rarely is done, the fact remains that it is the better part of wisdom to strain lubricating oil before it is put in the tank, not only to prevent the clogging of oil ducts and to eliminate the possibility of abrasive action due to foreign substances, but also to prevent foreign matter from getting into the pump. Such matter may cause the pump to stick and some part to become broken.

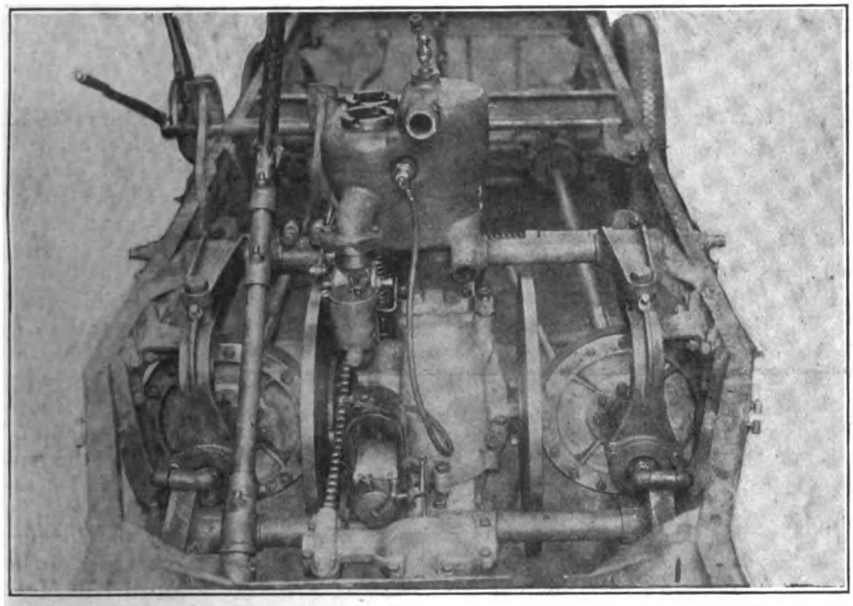
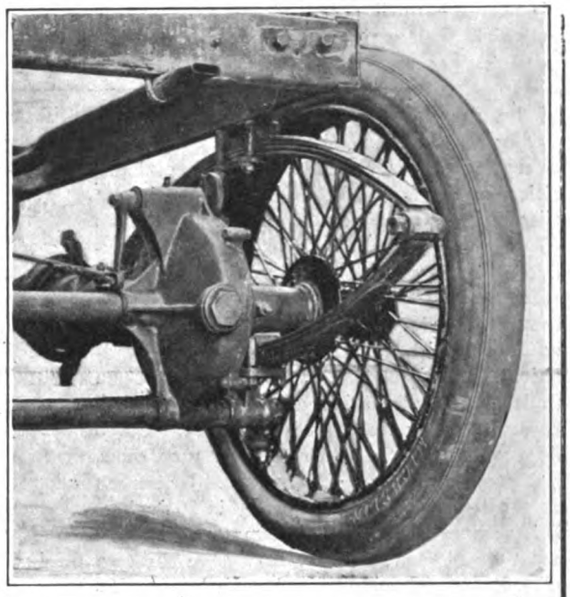
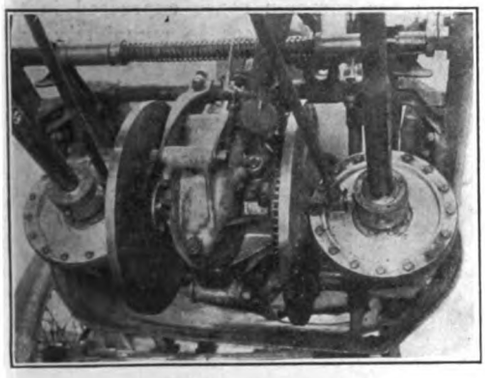
RADICALITY IN FRICTION DRIVE



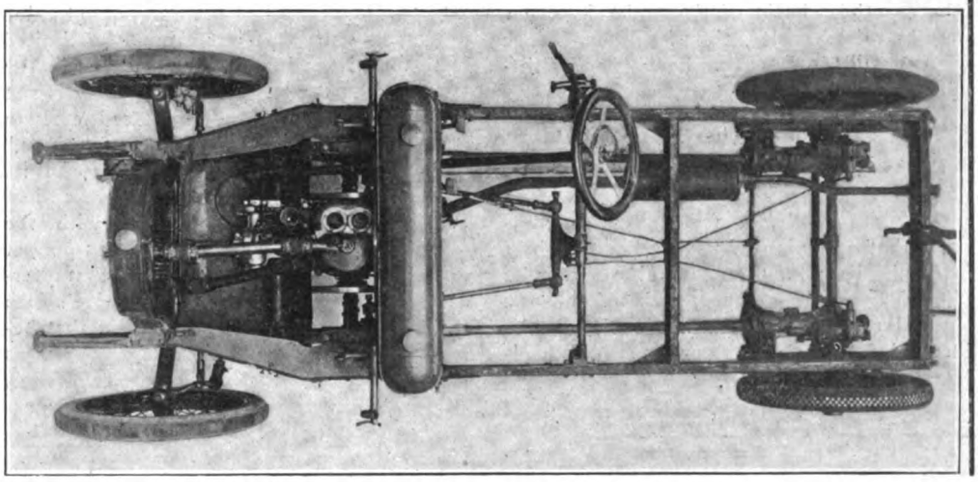
French Single Cylinder Production That Bristles With Amazing Features—Has No Flywheel and No Differential.



As outre as some French designs may be, to employ a French adjective—and some designs which are peculiar to say the least, as well as some very excellent ones, have come from the boards of French designers —it is a long time since a vehicle as absolutely unique as the Dumond car, which is illustrated herewith, has put in an appearance. Not only in one or two respects is the car unusual; it fairly bristles with features of a character that mark it as distinct from anything else that has been produced either abroad, where many of the radical departures from standard practice originate, or in America. Despite the radicalism of the car and its small size and power, however, that it has qualities that entitle it to recognition is evidenced by the fact that it completed the recently finished Tour de France without serious difficulty, a feat that was attempted without success by many larger and more powerful cars.



In its simplest aspect, the car is of the friction drive order, though the transmission elements are by no means as simple as those of some of the better-known friction-driven cars. For power, a single-cylinder L-head engine is used, and, contrary to the usual practice, it is arranged transversely in the chassis. Referring to the picture, it may be seen that the engine has no flywheel, as the word generally is understood. Instead, the two friction plates act as the flywheel, being made slightly heavier than is necessary merely to transmit the drive for this purpose.



From the engine, power is transmitted to the rear axle by means of two propeller shafts, at the forward end of each of which are located the friction disks which press against the flywheel plates. By means of an ingenious system of linkage, which is best made plain with the help of the pictures, the friction disks on the propeller shafts may be withdrawn from contact with the driving plates simultaneously. The driven disks are slidably mounted on the propeller shafts, and to obtain the various forward speeds and reverse are moved toward or away from the center of the driving members by means of linkage similar to that which is in common use in American friction-driven cars. No differential is provided, nor is one necessary, for the simple reason that when the car is rounding a corner one of the friction disks slips slightly on its driving member.

Following the usual practice, two sets of brakes are provided, one set being located on the propeller shafts. The location of the other set is unusual, however, in that the brakes are placed within the casings that house the two bevel drives. Thus they are completely enclosed and are thoroughly protected. In the matter of rear spring suspension also the car is unusual, the lower halves of the springs, which are of full elliptic type, being attached below the

axle. Instead of being attached directly to the axle, however, they are fastened to the axle brace, which forms a sort of second axle and carries the load.

Tiltings at Which Cars "Turn Turtle."

Though it is comparatively well known that the underslung type of car has slightly greater stability than the ordinary type of overhung car, there has been no lack of controversies over the relative stability of the two types. Neither type of car will topple over unless it is tilted at a considerable angle, though until recently the exact angle at which overturning might be expected has not been generally known. The tests which disclosed the fact were made at the factory of the Regal Motor Car Co., in Detroit, and demonstrated that the ordinary type of overhung car will return to its normal position on all four wheels provided it is not tilted sideways to an angle of more than 43 degrees; if that angle is exceeded, however, the car will "turn turtle." At any rate, that is the experience of the experimenters at the Regal facory, the car being equipped with a raised top and a windshield. Similarly, it was found that an underslung car, equipped with the same accessories, may be tipped to an agle of 60 degree 30 minutes before it will turn over, a difference of some 20 degrees. Inasmuch as the tread of a car generally is 56 inches, it is a comparatively simple matter to figure out that an overhung car may have the two wheels on one side raised a little over 38 inches from the road before it will capsize, whereas the wheels of the underslung car may be raised no less than 50 inches before the car will topple over. Each car was tilted until it balanced on two wheels.

Valve "Silencing" That Is Inadvisable.

It has been suggested, since the practice of enclosing the valve mechanism with a metal plate has become more or less common, that a section of rubber hose slightly larger in diameter than the valve spring be slipped over the valve springs of motors, the valves of which are not enclosed, the idea being to decrease the noise. It is needless to state that heat and oil are the two deadly enemies of rubber, and when acting in conjunction with the continual chafing of the valve spring, the very rapid disintegration of the hose would go a great way toward causing irregular valve action and consequent misfiring.

Why Carburetter Hole Should be Open.

The tiny little hole in the top of the bowl of a carburetter is put there for a definite purpose and should be kept open and free from obstruction. Its purpose is to equalize the pressure in the bowl with the pressure of the atmosphere and thereby prevent the possibility of a vacuum being formed in the bowl, which condition would seriously impair the efficiency of the carburetter. The hole is made very small to prevent the gasolene from slopping out, and should not be enlarged.

STILL BELIEVE IN POPPET VALVE

Two of Its Adherents Voice Their Sentiments—Commend Motor World for Its Article on Valve Mechanisms.

In any comparison of the poppet-valve motor with the non-poppet-valve motor, there are four factors which it is essential to consider. They are efficiency, as measured by the actual power output per unit of fuel; economy of operation, with due regard for both gasolene and lubricating oil consumption; simplicity of construction, and quietness of operation. Which, briefly, is the opinion of Nathan B. Wales, of Boston, Mass., expressed in commenting on an article which appeared last week in the Motor World, and in which the methods in vogue for quieting poppet valve mechanism was discussed under the title, "Quieting the Action of Poppet-Valve Mechanisms."

Though Wales has slightly overstepped the boundaries of the article, which was not intended as a comparison between the two types of engine, but merely as an exposition of some of the means which prominent manufacturers have adopted in quieting their poppet-valve mechanisms, he nevertheless raises several interesting points, and in the end comes right back to advocating further development of the poppet-valve mechanism as the real solution of the valve problem.

"The direct effect of the non-poppet valve on poppet valve design cannot be limited in terms of the increasing quietness in the operation of the poppet valve, which is not the main factor to be considered when a comparison, as such, is made between them," he writes. "The Knight engine, with its sliding sleeves, gives a perfect valve action, always in perfect synchronism with the cylinder at all speeds. Other non-poppet valves do the same, and it is this characteristic as compared to the poppet valve's cam and spring return valve mechanism that becomes the great determining factor, as shown in the power curves of the two types.

"The power curve of one of the oldest and best-rated makes of six-cylinder engines shows a maximum power point at 1,700 r.p.m., which is very good for the cam and spring-return operating mechanism of the present poppet valve. It will be noted also that the 'curve' starts to bend from a straight line, showing a decreasing rate of power developed, as compared with the increased r.p.m. at 500 r.p.m., while in contradistinction the power curve of a positively operated valved engine will maintain a straight line in its 'power curve' up to a far higher r.p.m., showing proportionally increased power with increased speed.

"What does this mean but that with a like bore and stroke as in a poppet-valve engine, a positively operated valved engine can be geared on direct drive to a ratio of 5 to 1, whereas the average poppet-valve engine is geared around 3 to 1. This is possible, as the positive valved engine can be operated through a wider range of r.p.m. so that it may come down to two miles an hour on high gear, and at the same time go up to sixty miles an hour without changing gear; moreover, operating under a 5 to 1 direct gear drive gives a 'feel' and 'hang-to' on a hill that would surprise the poppet-valve engine driver.

"Now, if a poppet valve, as such, could be operated in its intermittent action with periods of 'rest' and sudden movement by a positive valve mechanism which could operate through high ranges of speed without losing 'step' with the piston and without the flutter as now seen in the cam and spring-return mechanism at high speeds, we then would have made a great step in advance, for we would have a positive operated valve, as in the Knight, combined with a type of valve that is essentially simple and can operate without constant lubrication."

Nor is Wales alone in his opinion as to the direction in which it is best to look for that perfection of valve mechanism toward which all are striving. H. A. Moyer, of Syracuse, N. Y., whose carriages have made a reputation for themselves that bids fair to be equalled, if not excelled, by the reputation of his automobiles, also holds that in the poppet-valve motor there still remains excellent material for development.

"I have noted with a great deal of interest your article in the April 11th Motor World on 'Poppet-Valve Mechanism,'" Moyer writes, "and also your editorial on the poppet valve. I am particularly pleased with the common sense expressed in the editorial, as it agrees so completely with my theories and opinions on the poppet-valve motor.

"I have often made the remark that the manufacturers of the other kinds of gasolene motors ought to have made a good poppet-valve motor before they took up anything else, and I think it will be found that it will be a long time before they will get any poppet-valveless motors that will cause to be discarded a good, carefully built poppet-valve motor. I am manufacturing for my cars a new poppet-valve motor that is built with every possible care and as fine as can be produced."

With regard to poppet-valve mechanism in general, Moyer adds: "It is a great deal more sensible and decidedly simpler than the complicated mechanism of a sliding valve system. With a poppet-valve mechanism that is made with every possible care, and just as fine as it is possible to make it, as satisfactory results can be obtained as anything that has as yet been developed in any other type. I feel that time will show that this principle of a gasolene motor will not be discarded in favor of anything that has as yet not been developed. As in the words of your editorial, 'The poppet valve motor can be made, and is made, as silent and as efficient as can be desired.'

"I therefore want to congratulate the

Court Stops Slow-Going Undertakers.

It would look very much as though the Louisville (Ky.) Funeral Directors' Association, affected by the pace of its funerals, was lagging behind the times, for not long since it passed a solemn by-law prohibiting the use by its members of motor cars for business purposes. While the association as a body might have been lacking in appreciation of motor vehicles, there was at least one individual member, L. D. Bax, who did not scruple to add one to his equipment, whereupon the association threatened him with suspension, in accordance with the rules and regulations. Failing to see the matter in the same light, however, Bax took the matter into court, which just has granted him an injunction perpetually restraining the slow-going association from interfering with its ultra-modern member.

"Doctor" Whose "Practice" Was Peculiar.

That Dr. Alan T. Gentry, of Morristown, N. J., made a business of selling stolen motor cars, is the charge lodged against him by the detective department of the Jersey town. The physician was arrested by the police late last week, after a serious accident, and now is held under $15,000 bail. He was known in Morristown as a doctor who preferred not to practice his profession, although he treated a few patients, and most people knew him better as an automobile salesman. The cars he sold, however, are said to have been stolen in Philadelphia, Hoboken and various other neighboring cities, where, according to the testimony of some chauffeurs, he was known as "Williamson."

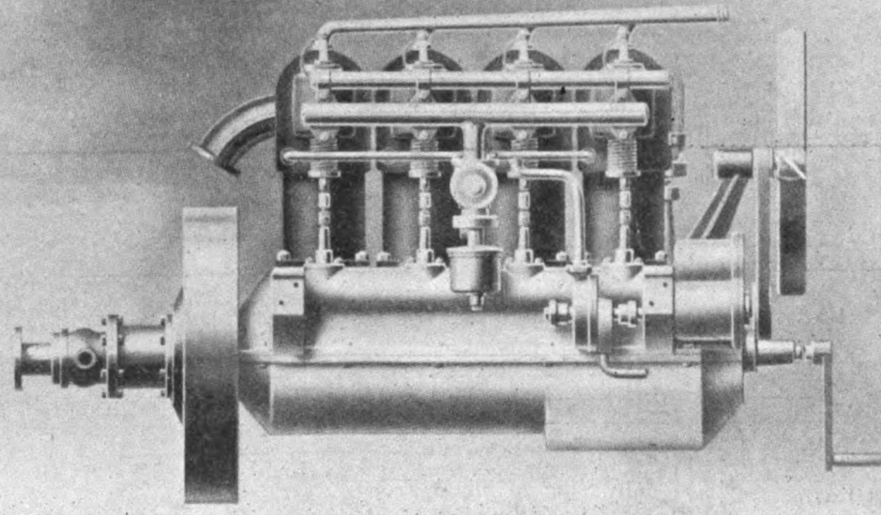
Jencick Quality

POUND for pound, the commercial truck engine must possess greater endurance than the pleasure car motor. This is the policy back of Jencick design and construction.



Jencick motors are simple, powerful, silent, flexible—not in promise, but in every-day performance.

1,004,836. Air Cooled Explosion Engine. Alven E. Walcott, Lowell, Wash. Filed Dec. 1, 1909. Serial No. 530,825.

1. In an explosion engine, the combination with an explosion cylinder and piston working therein; a compression or circulation cylinder of larger diameter than said explosion cylinder; a passage connecting said cylinders to convey the cold compressed air from the compression cylinder to the explosion cylinder when the passage is opened; and a piston formed integral with the piston in said explosion cylinder and fitting said compression cylinder whereby a greater volume of cold air is forced into the explosion cylinder than is displaced by the piston therein.

1,004,850. Windshield. Joseph Cogil, Central City, Neb. Filed Mar. 23, 1911. Serial No. 616,548.

1. In a windshield, a body frame and a head frame, means for hingedly connecting said frames together, a frame covering for said frames, a transparent member carried by the frame covering over said head frame, and means for suspending the aforesaid parts on a user.

1,004,867. Vehicle Tire. Samuel H. Gilson, Salt Lake City, Utah, assignor of one-half to Jay S. Milner, Salt Lake City, Utah. Filed May 2, 1911. Serial No. 624,671.

1. In a vehicle tire the combination of a metal band having peripheral flanges thereon and forming a shoulder near each edge of said band, a disk band adapted to fit on each of said shoulders, transversely alined slots cut in said disk bands, the outer edges of said slots being tangential to said metal band, concentric resilient bands adapted to fit between said disk bands, transversely placed lugs firmly secured around the outer of said resilient bands, sleeves on the outer ends of said lugs adapted to move within said slots, a plurality of transversely placed lugs on the other resilient bands, and a laminated tread engaging the lugs on and firmly secured to the outer of said resilient bands.

1,004,895. Tire. De Witt Nelson, Minneapolis, Minn., assignor to E. J. Phelps, Minneapolis, Minn. Filed Jan. 19, 1907. Serial No. 353,152.

1. A tire of the character set forth, comprising a series of corresponding sections, reinforcing plates applied to the opposite sides of the sections, and second plates secured to the reinforcing plates and carrying means for detachably connecting the sections.

1,004,907. Automobile. Charles F. Rodin, San Francisco, Cal. Filed Apr. 11, 1910. Serial No. 554,819.

An automobile having in combination two pairs of wheels, located near the rear and two pairs near the front of the machine, turnably journaled transverse shafts, and transmitting mechanism to rotate all the shafts in unison, the rear shaft having immovable bearings and having wheels fixed to its ends, the center of said wheel shaft being the radial point upon which the frame swings bodily, and the other shafts having jointed extensions to which the bearing wheels of said shafts are secured, rocker arms fixed to said jointed wheel shafts, a steering mechanism, a longitudinally journaled shaft turnable in unison with the steering wheel, rocker arms fixed to the longitudinal shaft and decreasing in length from the front to the rear, and connecting rods between said shaft and the rocker arms of the turnable wheels, whereby said wheels may be proportionately turned independently of the rear pair of wheels.

1,004,950. Tire. Howard O. Wilson, Ainsworth, Neb. Filed Dec. 3, 1910. Serial No. 595,398.

1. A wheel having a substantially cross sectional U-shaped felly, a tread member also of a substantially U-shaped cross sectional formation straddling the felly, resilient members positioned between the sections, spokes for the said wheel, the inner face of the said felly being formed with a plurality of doors adapted to provide means whereby access to the resilient members may be had for the purpose of repairing the same, each of the said doors positioned between the spokes, and a means to retain the doors in locked positions.

1,004,953. Automobile Headlight. John H. Adams, New Haven, Conn. Filed Feb. 18, 1911. Serial No. 609,283.

1. In an automobile headlight, the combination of a clip applied to the axle, a lamp bracket mounted to turn about a vertical axis, a connection between the lamp bracket and rod connecting the arms of the steering knuckles, said connection comprising separable parts, one of which is adapted to be supported in the aforesaid clip when disconnected from the other part, and a fastening for detachably connecting the parts of the connection.

1,004,964. Dirigible Headlight. George John Baker, Republic, Pa., assignor of one-half to Peter Lacey, Republic, Pa. Filed June 30, 1911. Serial No. 636,164.

1. In a dirigible headlight for automobiles, the combination with side frames, an engine hood, and the wheel spindles of the automobile, of converging arms supported by said frames and said hood, a yoke carried by the forward ends of said arms, a post revolubly mounted in said yoke, lamp brackets detachably mounted upon said post and adapted to support a lamp, a sprocket wheel mounted upon said post within said yoke, inwardly projecting arms carried by said wheel spindles, and a flexible connection between said arms and including a sprocket chain passing around said sprocket wheel.

1,004,966. Demountable Rim. Frederick R. Barker, Boston, Mass. Filed Aug. 19, 1910. Serial No. 578,045.

1. The combination with a wheel, of a rim, a gear, a pair of racks oppositely meshing with said gear, means operated by said racks for securing said rim to said wheel, a ratchet connected to said gear, a pawl engaging said ratchet, a lever on which said pawl is mounted to move relative to said lever and bodily with respect to said ratchet, and means to normally lock said lever.

1,004,973. Automobile Steering Mechanism Lock. George W. Benton, Finley, N. D. Filed Jan. 26, 1911. Serial No. 604.803.

In a device of the character described, the combination with the steering mechanism, front axle and steering knuckles of an automobile, of a toothed bar fixed on said axle, a movable toothed bar connected to one of the steering knuckles, and means for forcing the teeth of the movable bar into engagement with the teeth of the fixed bar, whereby the movable bar is locked against movement under the influence of the movement of the steering knuckles to which it is connected.

1,004,979. Internal Combustion Engine. Otto Leo Borner, London, England. Filed Sept. 23, 1907. Serial No. 394,087.

1. Means for expelling products of combustion from a two-stroke cycle internal combustion engine, comprising a main inlet through which part of the charge is admitted to the engine cylinder, an auxiliary inlet through which the remainder of the charge is admitted at predetermined variable times and separate means for controlling said inlets.

1,004,984. Gas Engine Starter. George Buress, Indianapolis, Ind., assignor of one-half to Robert Long, Indianapolis, Ind. Filed Nov. 18, 1909. Serial No. 528,690.

1. In an automobile, the combination with an engine, an engine shaft, and a fly wheel adapted to actuate said shaft, of an annular ratchet on the side of the fly wheel, a bell crank lever mounted beside said ratchet, a pawl pivoted to one arm of the bell crank and adapted to engage the ratchet, means connected with the other arm of the lever for actuating it, a spring for returning said lever and pawl to their normal positions, and a pawl for engaging the ratchet and preventing backward movement thereof, substantially as set forth.

1,004,986. Safety Valve for Pneumatic Tires. Bruce Burkett, Burkett, Tex. Filed Jan. 18, 1911. Serial No. 603,326.

In a valve structure of the class described, a casing, a valve seat therein at one end, an adjustable member engaged with the casing at the opposite end, a hollow stem extending through the casing and movable in the adjustable member and having an outer portion extending beyond the adjustable member, a cap removably engaged with the outer portion of the stem, the inner portion of the stem being interiorly threaded, an upwardly projecting exteriorly threaded portion formed integral with the said valve and threaded into the said stem, a spider formed integral with and interiorly of said upwardly projecting portion, a valve carried by the spider, a spring located in the casing and adjustable between the adjustable member and the valve and operating to normally hold the valve closed against the said seat, said valve having a central valve seat therein, an inwardly opening valve movable in the first valve, a stem carried by the second valve and extending through the spider, a nut adjustable on the second stem, and a spring interposed between the spider and the nut and operating to hold the second valve normally closed against the seat in the first valve, the said casing having a portion immediately adjacent the valve seat of a diameter greater than the diameter of the first valve and formed with a passage.

1,004,988. Vehicle Wheel. John Callan, Globe, Ariz. Filed Dec. 1, 1910. Serial No. 595,087.

1. A wheel comprising a hub, a cushion encircling the hub, a rim having recesses in its inner periphery, plates fastened to the rim over said recesses, said plates having sockets which open into the recesses, spokes, heads carried by the spokes adjacent to their outer ends, said heads seating in the sockets of the aforesaid plates, and the ends of the spokes extending through said sockets into the recesses of the rim, and shoes carried by the inner ends of the spokes, said shoes engaging the aforesaid cushion

1,005,021. Resilient Wheel. Vicente Gil-Delgado y Olazabal, Madrid, Spain. Filed Oct. 27, 1908. Serial No. 459,694.

Digitized by Google

A resilient wheel comprising outer and inner disks of equal size arranged parallel and co-axial with each other and provided with slots, radial ridges on the outer face of the outer disk and forming inwardly disposed shoulders, a ring resting against said shoulders, a movable member arranged between said disks, radial slots in said member, crossing the slots of the disks, studs passing through said member and engaging in said slots, a hub having a flange and passing through the center of said member, bolts passing through said flange and member, a rim on said bolts, sleeves on said bolts and holding said rim spaced from said member, a tire on said rim and engaging said ring, and screws radially adjustable at their ends in said slots for limiting the movement of said studs.

1,005,035. Tachometer. Max Hoeft, Berlin, Germany. Filed Aug. 19, 1908. Serial No. 449,295.

1. A printing device to record the speed of a vehicle and the like, comprising in combination, type wheels operated in accordance with the speed of the vehicle, mechanism to print from said type wheels, a mechanical part continuously moved by the vehicle, and means to couple said mechanical part with said mechanism, substantially as, and for the purpose, set forth.

1,005,041. Antifriction Bearing. Charles O. Johnson, Boston, Mass. Filed June 30, 1909. Serial No. 505,130.

1. In an anti-friction bearing, the combination with an axle, of a cage surrounding the axle and comprising two connected rings each having a ball-receiving groove in its outer side face and each having ball- receiving openings through the inner wall, a washer in the bottom of each groove, bearing rollers situated between the rings and provided with recesses in their ends, balls received partially in the recesses in the ends of the bearing rollers, and a series of balls in the ball-receiving groove in the outer side face of each ring.

1,005,045. Starting Device for Internal Combustion Engines. Robert Owen Le Baron, Portsmouth, Ohio. Filed Jan. 25, 1911. Serial No. 604,520.

1. In a starting device for internal combustion engines a conduit member having two branches, a valve for connecting one of the branches with the other, and with the conduit, one at a time, a second conduit connected with the first conduit, and a check valve in the first conduit between the first-mentioned valve an dthe second conduit.

1,005,080. Supplemental Seat for Motor Cars. George H. Storm, New York, N. Y., assignor, by direct and mesne assignments, of one-half to Philip Willoughby Masi and one-half to Cora Sinclair, New York, N. Y. Filed Feb. 14, 1911. Serial No. 608,552.

1. A supplemental seat for a motor car having a running board, comprising a horizontal bar having inturned end portions capable of connection with the car to leave an interval between said bar and said car, a seat having lengthwise-adjustable pivotal connection with said bar, and a standard having a lower inturned forked end capable of detachably embracing the edge of the running board and an upper forked end capable of detachably embracing the outer frame bar of said seat.

1,005,103. Wheel. Thomas S. Chestnut, Buffalo, N. Y. Filed Dec. 29, 1910. Serial No. 599,855.

1. A wheel comprising a hub, a rim, a plurality of thrust receiving and transmitting load sustaining spokes arranged tangentially of the hub and connecting same with the rim, and a plurality of draw spokes connecting the rim and hub, whereby the former may be drawn toward the latter and the load sustaining spokes tightened.

1,005,118. Method of Operating Internal Combustion Engines. William Rabsilber, New York, N. Y. Filed Nov. 21, 1910. Serial No. 593,337.

1. A method of operating an internal combustion engine which consists in running the engine by compressing and burning in the combustion chamber thereof carburetted air and thereby energizing the piston and warming the walls of the combustion chamber; subjecting fuel to the heat of combustion generated in the combustion chamber; reducing the carburization of the air to a degree so low that preignition cannot take place at high compression; increasing the compression to a high degree; and injecting the preheated fuel into air in a highly compressed state in the combustion chamber, after the walls of the latter have been warmed.

1,005,121. Circuit Interrupter. Christian Aalborg, Wilkinsburg, Pa., assignor, by mesne assignments, to Westinghouse Electric & Manufacturing Company, East Pittsburgh, Pa., a Corporation of Pennsylvania. Filed Oct. 7, 1908. Serial No. 456,579.

1. In a circuit interrupter, the combination with stationary and movable contact members, of a liquid-containing casing in which the members are disposed having an enlargement at the surface of the liquid for increasing the cross-sectional area at this point.

1,005,135. Windshield. Arthur L. Banker, Pittsburgh, Pa. Filed Dec. 18, 1907. Serial No. 406,969.

1. The combination with a sectional windshield, of means for hinging the opposing side frame members together comprising at each end a pair of co-operating transverse blocks hinged together at one of their ends and means for securing the other ends together comprising a locking lever pivoted to one block and having an inclined camming surface adapted to engage the end of the other block and a screw extending through the said lever and bearing at one end upon the side frame member for securing the lacking lever in locked position.

1,005,136. Windshield. Arthur L. Banker, Pittsburgh, Pa. Filed July 15, 1910. Serial No. 572,204.

1. In combination in a windshield, a lower frame member, a bearing block at each side thereof having a recessed face and a glass clip to the rear of the recess and projecting above the face of the block, a glass carried by the clips, an upper frame member, a bearing block at each side thereof hinged to the opposing bearing block on the lower frame member and having a recessed face and a glass clip to the front of the recess and projecting below the face of the block, a glass carried by the clips, and means for holding the shield in upright position.

1,005,170. Running Gear for Motor Vehicles. David M. Dearing, Jackson, Mich. Filed Nov. 12, 1909. Serial No. 527,623.

1. In a running gear for vehicles, a front supporting axle, a supporting frame terminating at the inner side of said axle, a substantially Y-shaped cross head with the shank thereof rotatably mounted in the forward end of said frame and with the arms arranged in horizontal position and yielding connections between said arms and said axle, said connections being arranged on opposite sides of the center of the axle and radius rods connecting said axle with said frame.

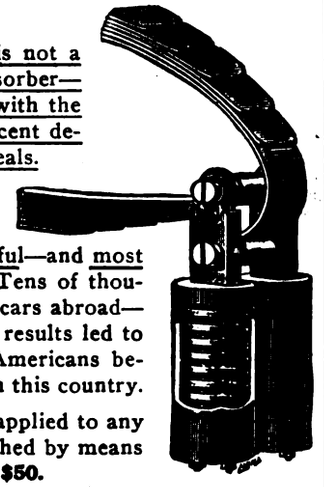
SHOCK ABSORBER

THE RAGE IN ENGLAND

TRADE MARK

Learn at our expense



how to get the maximum of comfort and wear out of your car

"J. M." Shock Absorbers

—patented in all civilized countries—

give you greatest comfort, because they prevent jolting and jarring from stones, ruts, car-tracks; swaying and rocking from uneven roads, when traveling at good speed;

save expense, because your tires are kept on the ground, do not whirl at high speed in the air to be suddenly slowed upon return to the road and consequently the "J. M." increases largely your engine efficiency as well as tire service.

Note that the "J. M." is not a "rotary friction" shock absorber—and is not to be confused with the devices embraced in the recent decision of the Court of Appeals.

Experience in Europe has proven that the "J. M." is the most successful—and most efficient—shock absorber. Tens of thousands have been placed on cars abroad—and the highly satisfactory results led to the sale of many sets to Americans before we had any branches in this country.

Made in three models—applied to any car whose springs are attached by means of shackles. **Prices $35 to $50.**

Try it on your car—don't pay us a cent till it proves our claims. Send coupon below, pinned to your business letterhead, for booklet W and full information on this offer. Mention the name, model, weight and width of rear springs of the car you run.

The "J. M." SHOCK ABSORBER CO.

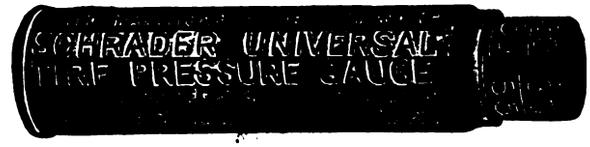
DEALERS — GET OUR ATTRACTIVE TRADE PROPOSITION
DESIRABLE TERRITORY STILL OPEN

Mr. Automobilist:

Your tire maker is very anxious to impress upon you the importance of

Tires Inflated to the Right Pressure



He insists that this is tire economy and

Saves You Money

How do you know what pressure you have in your tires? A

SCHRADER UNIVERSAL Tire Pressure Gauge

(Trade Mark Registered in U. S. Patent Office)

(Patented March, 1898—Other Patents Pending)

will tell the exact pressure in your tires at any time, day or night, by simply holding this Gauge to your Valve for a second. Its recording sleeve remains in place, showing the exact pressure in the tire so that the Gauge can be taken anywhere and read, at night to the front of the car into the light of the lamps. After the pressure has been ascertained the Indicating Sleeve can be pushed back into the Gauge with your finger. No catches or snaps to operate or get out of order. This Gauge is 2½ inches long over all, short enough to apply easily to the smallest diameter of wheel and can easily be carried in the vest pocket or the change pocket of your trousers.

Price $1.00 Each

BOSCH

STANDARD OF THE WORLD

ONE MILLION MAGNETOS

THE experience gained during the production of 1,000,000 perfect magnetos is experience that no other but the makers of Bosch Magnetos can claim. It is the basis of the confidence that a million Bosch owners display; it is the REASON WHY every Bosch Magneto bought will be a success, not for today or tomorrow only, but for a period exceeding the life of the engine itself. "One Million Bosch Magnetos produced and in actual use" is an important statement, a fact bearing considerable significance for every user of a car or internal combustion engine. What is good for a million is good for you.

THINK THIS OVER

very carefully and read it twice, if necessary.

Is there any part of an automobile engine, or any other gas engine, that is more important to its efficiency than a Valve?

Your engine leaves the factory running smoothly and sweetly—tuned up to its highest power. Perhaps the valves pit—warp - go out of shape—fail to hold compression. Then the power diminishes, and what can be more aggravating to the driver, who has known the fullness of the pulling power of his motor, than to have it grow less and less?

You cannot slight this part by putting in an inferior product—valves that will give trouble, or even break from inexperience in their manufacture—valves of unsuitable material, not suitably heat treated.

Too much is at stake, and a slight extra cost at the outset, which is the exception, may save you many times over a probable later expense.

This Company, with the experience of many years as a guarantee, will furnish you with properly made valves, of the materials best adapted to your requirements.

Not only QUALITY, but efficient SERVICE is a factor—surely there is a satisfaction in getting the kind of work you want—when you want it.

WHITNEY

The Most Practical Chain for Motor Trucks

Because the "Whitney" Cotter Detachable Chain can be easily separated at any link and lengthened, shortened or repaired without the use of any special tool. This is of great advantage to truck builders, owners and drivers.

To have your truck equipped with "Whitney" Chains means greater mileage because they are made by specialists in a factory especially equipped for the making and are backed by years of experience. "Whitney" Chains are made from material chosen for quality regardless of cost, and all care taken in their manufacture makes them stand foremost. When making replacements try a "Whitney" and get acquainted with its merits.

The Reflex

The Eye Can Pierce the Darkest Recesses

of the automobile through the use of the Reflex—a powerful hand electric light with an adjustable mirror.

This unique and most useful little device is meeting with a ready sale not only among car owners, but in garages and repair shops where, during many times in the day it becomes necessary to inspect some hidden part of the automobile—does away with the danger incident to the use of matches or candles in proximity to the gasoline.

The current for the light is furnished by a small but powerful battery, located in the handle, and one charge is sufficient for hundreds of inspections.

Write today and get a full description of the Reflex together with our prices to dealers.

If you sell motor car appliances, you will find this lighting device to be one of your steadiest and best sellers ,after it has once been introduced.

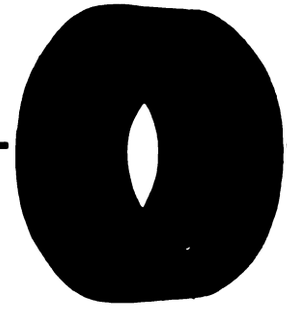
Let Your Motor Inflate Your Tires

It's not necessary for you to break your back and spoil your temper trying to inflate your tires with an old-fashioned hand pump.

Get a Brown Impulse Tire Pump

and let your motor do the work. It takes but a moment to remove the most convenient spark plug and screw in the Brown Impulse Pump. No tools are necessary.

One to four minutes inflates with pure, cool air to any pressure up to 150 lbs.



No complicated parts, nothing to wear or get out of order. Will last a life-time.

Enjoy your car this year. The Brown Impulse Tire Pump removes the most disagreeable feature of automobiling. Price, $15.00, including 12 feet of hose, HIGH GRADE RECORDING GAUGE and SELF OPENING VALVE CONNECTION.

An essential part of your 1912 equipment. Ask your dealer or write us for full information.

Announcement

TWITCHELL AIR GAUGE

The Twitchell Gauge Co. have succeeded the Twitchell-Garvey Mfg. Co. and will in the future market the Twitchell Tire Pressure Gauges.

All patents, rights, etc., including the Twitchell trade name, have been taken over by this firm. Our rights and yours will be vigorously protected under Twitchell patent No. 927,298, which has been repeatedly adjudicated as valid by the courts.

The fine quality of workmanship and accuracy which has distinguished the Twitchell Gauges in the past will be maintained in the future, and this Gauge with the new stop feature, which has been perfected by Mr. Twitchell, is now ready for the market and will thus continue to be the leading Tire Pressure Gauge, as it has been since it first was put on the market.

Mr. Fred G. Bremer has succeeded Mr. James Garvey as manager of this firm.

K·D

The Motor With the Sliding Crescent Valve

KNIGHT-DAVIDSON

1896 — 1912

The CRESCENT valve of the K-D Motor, fitting around the stationary piston wall affords a larger port area than any other poppet or slide valve on the market. It is simpler and, consequently, better than any other valve construction known and is here offered to discriminating manufacturers, not as an experiment, but as a tried, tested and proved mechanical advance. The K-D motor is simple, silent, cools rapidly, has the simplest oiling system known, will not carbonize. Last and most important, will give on a given quantity of fuel more power, speed and endurance, unit for unit, than any other engine on any type of an automobile. We want to present some facts to interested manufacturers.

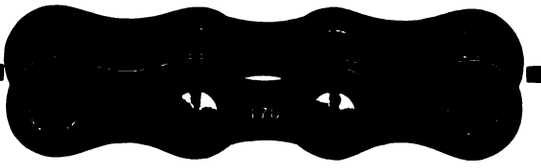
The Motor Lamps with Distinctive Features

There are no other motor lamps on the market with the advantages of Solar Lamps. Solars are always exclusive in style and in quality. They are the strongest lamps as well as the most effective.

In no other lamps can you obtain the Solar Special Short Focus Lead Glass Lens Mirror Reflector—the patented system of double ray light projection which gives two distinct fields of light for town and country use—or the new and exclusive black finish with a metallic lustre which is unaffected by heat or moisture. All of these features are exclusively "Solar."



Do not equip your car or specify equipment to the maker until you have seen all of the Solar advantages. See Solars at any live dealer's or write for the catalog.

Solars are made in all styles for oil, electricity, gas and in combinations.

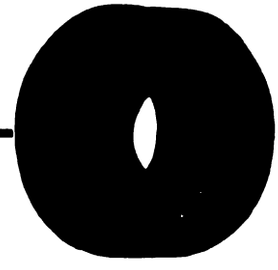
MAY WE HAVE YOUR LAYOUT

Of Bearing Installation?

¶ We can save you money, time and trouble—in other words, show you a short cut to satisfactory bearing installation.



¶ The successful use of New Departures in 60% of the motor cars manufactured in this country proves that the quality of this American made bearing has been well established.

¶ This fact also constitutes a good reason why you should send us your layout and give our engineering and sales departments an opportunity to place our proposition squarely before you.

¶ Our engineering department is highly specialized, not only for the production of superior ball bearings, but for giving to the trade expert co-operative service.

Sanford

Chassis
$1600

Stake or Express Body
$1750

The more rigid the test—the closer the investigation—the higher this standardized truck stands in the buyer's mind.

Sanford trucks are built to harmonize delivery departments of successful firms with the other departments. Sanford trucks installed assure delivery at the right cost.

Sanford trucks represent nine years designing and building. They are the finished product of all those years of thought and labor by the present engineering staff of the Sanford Motor Truck Co.

No truck can offer a greater factor of safety all through its construction than a Sanford. No truck could be better built. No truck is so thoroughly standardized as is the Sanford.

No manufacturer has ever offered to dealers so remarkable a proposition as we offer.

Ample motor capacity (4 cylinders, water cooled, 4 x 4½), unit power plant type, three point suspension, with clutch and fly wheel enclosed in oil tight aluminum housing.

The service brakes are on the rear wheel brake drums and operate positively and equally on a braking surface of 245 square inches—braking backward as well as forward. The emergency brakes operate on the jack shaft drums.

Positive and never failing lubrication. A combination of splash and force feed. The Sanford system provides oil by force directly upon all bearings inside the clutch.

As to accessibility—well, we sometimes think that our truck was designed around this absolute essential. No truck could be more accessible than the Sanford in any one specific part or in any one specific assembly or in an entire assembly.

We have the truck and the proposition. All we need now is you. YOU need us. You'll say so yourself if you'll write us immediately. Don't wait. Write today for we're after your territory with both feet.

"The Horn that's Made for the Discriminating"

TUTO HORN

THE TWO TONE HORN

A Common Sense Signal.

THAT the TUTO horn has added greatly to the ease and safety in touring, is best shown by the many words of commendation which have been voluntarily given. Thousands of these horns were used throughout the past year in touring in this and foreign countries, proving conclusively that the notes of the TUTO horn are sufficiently distinctive to clear the way and assist in avoiding the many accidents incident to such travel.

¶ The extreme ease with which the TUTO horn is operated through the placing of a push button on the steering wheel and right under the thumb, is in strong contrast to the usually laborous and ineffectual working of the old antiquated bulb horn.

¶ Then the providing of two distinct and separate tones in the one TUTO mechanism, has made it possible for tourists to sound a low abrupt signal, which is acknowledged to clear the way fully 90 per cent. of the time, without causing undue disturbance and the incurring of the displeasure of local police authorities in the various cities.

¶ The loud note of the TUTO horn, being instantly available by a complete pressure on the same button as used in producing the low tone, assures the utmost safety.

¶ The fact that it is not necessary to always blow the loud signal or to juggle with a button in the attempt to get a low note from the one-tone loud electric horn, adds greatly to the pleasure of touring

¶ The occupants of the car are not continually being unnerved by the racking and useless noise of a warning signal which is inadequate, due to the fact that it has only one loud note for use on all occasions.

¶ The TUTO makes motoring easy, adds to the comfort and safety and thus is the only logical signal to use for standard equipment on the modern motor car.

The "Crankless" STARTER

With this new improvement the Crankless admits no equal.

By adding an injector and set of cylinder connections to the original crankless manifold connection, we now offer unquestionably the last word in self starters.

Now we guarantee to start your motor every time—guarantee it with the standing and reputation of our forty years in business.

Just press the button with your foot—nine times out of ten your motor will start. That other time, force gas and air into your cylinders—and away you go.

The pump is like the spare tire—when you don't need it—don't use it. But when that "once-in-a-while-that-you-do-need-it" comes, it's fine business to have the injector handy.

There's absolutely nothing on the market that can compare for one second with this improved Crankless.

It's the simplest—the safest—the surest starter ever devised.

And the price is right—and our guarantee is good.

The Story of the Tell-Tale Dial

Upon the wall of the factory chief's room is a little instrument on whose dial a story is written each day.

A tale white-hot with interest to the man with the key to its meaning. It's a story of faithfulness in the heat-treating of

The instrument with the tell-tale dial is a recording pyrometer.

It is connected each day and each night with one of the heat-treating furnaces—which furnace only the chief himself knows.

Wires lead from the electric resistance thermometer in that furnace to the pyrometer on the chief's wall.

Clockwork and the current operate a pen which records in clear-cut lines the temperature for every minute and hour of the time.

A Check on Other Records

Out in the furnace room is another pyrometer. That one is for the man who reads the temperature of all the furnaces each quarter of an hour.

He is the man whose signals of red, white or green light at each oven tell the furnace man how to regulate his fire and when to remove the glowing steel.

Now, who is to prove that the work is done right? Who knows that no one has cooled the furnace by opening its door in the night?

Answer—The tell-tale dial.

Timken Heat-Treatment is an Exact Science

Each piece in the Timken-Detroit Axle has its particular heat-treatment.

The one treatment which will bring out the best that is in the kind of steel used for the particular work each piece must perform.

Long experience and careful records of results have determined the exact degree of heat and exact length of time for each part. *And the dial tells that the work is done right.*

The story of the dial is one of the interesting stories in Timken-Detroit manufacture.

It is this back-of-the-scenes integrity of manufacture—this extreme care in every process—that produces axles which stand up to the gruelling test of service day after day and year after year over all kinds of roads.

The Timken-Detroit Axle Company

Detroit, Michigan, U. S. A.

Which Tire?

No-Rim-Cut Tire
10% Oversize

Here is the Goodyear No-Rim-Cut tire—the hookless tire—the oversize tire.

The tire that cuts tire bills in two.

More than one million have been tested out. As a result, this tire outsells any other tire in existence.

The Passing Type
No Oversize

This is the old type—the hooked-base tire—which No-Rim-Cut tires are displacing.

23 per cent of these tires become rim-cut.

Yet these tires—wasteful and worrisome, and of lesser capacity—cost the same as Goodyear No-Rim-Cut tires.

Hookless Tires

Note that these tires have no hooks on the base. They do not, like old types, need to hook into the rim flanges.

So your removable rim flanges are slipped to the opposite sides. Then they curve outward, not inward.

This tire, when wholly or partly deflated, rests on a rounded edge, and rim-cutting is made impossible.

126 Braided Wires

In the base of this tire run six flat bands of 126 braided wires.

They are vulcanized in to make the tire base unstretchable.

The tire can't come off because the base can't give. Nothing can force it over the rim flange. So hooks or tire bolts are not needed.

But, when you unlock and remove one of the flanges, the tire slips off like any quick-detachable.

It slips off much easier, because there are no hooks to "freeze" into the rim flanges.

10% Oversize

To take care of your extras—to give you an overtired car—we make these tires 10 per cent. over the rated size. And without extra charge.

That means 10 per cent. more air—10 per cent. added carrying capacity. That saves the blow-outs due to overloading. This 10 per cent. oversize, under average conditions, adds 25 per cent. to the tire mileage.

We Control It

This braided wire feature, which makes this type possible, is controlled by the Goodyear patents.

Single wires have been used—twisted wires have been used—to get this unstretchable tire base. But results are unsatisfactory.

These bands of braided wires, which need no welding—which cannot break or loosen—form the only way known to make satisfactory tires of this type.

No-Rim-Cut tires are satisfactory. Be careful to get them when you change to this type.

On Same Rims

This old type tire—this clincher tire—is on the same rim as the No-Rim-Cut tire.

All standard rims take either type.

But the removable rim flanges are here set to curve inward—to grasp the hooks in the tire base and hold the tire on.

When this tire is wholly or partly deflated the thin edge of the flange digs into it. That is the cause of rim-cutting.

GOODYEAR
No-Rim-Cut Tires
With or Without Non-Skid Treads

If this tire is punctured or run soft, it may be wrecked very quickly, and beyond repair.

Doubled Cost

This type of tire, under average conditions, means to double one's tire cost over our new type.

It comes in this way:

Statistics show that 23 per cent. of all ruined clincher tires are rim cut.

And the smaller capacity, with the average car, cuts tire mileage 25 per cent.

These are net losses, because No-Rim-Cut tires now cost no more than other standard tires.

The 13-Year Tire

Goodyear tires as made today are the final result of 13 years spent in tire making.

We have compared in that time some 240 formulas and fabrics. We have compared every method of wrapping and vulcanizing.

They have been compared on tire testing machines, where four tires at a time are constantly worn out under all sorts of road conditions.

Thus we compare all rival tires with our own.

The result is a tire which comes close to finality.

When this tire is made oversize—made so it can't rim-cut—it means the utmost in pneumatic tires.

Some 200,000 tire buyers have proved this. No-Rim-Cut tires have thus become the most popular tires in existence.

Our 1912 Tire Book, based on all our experience, is filled with facts you should know. Ask us to mail it to you.

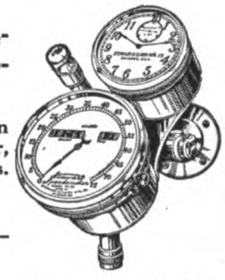
Toadstools and Mushrooms Look Alike

But you can tell the difference the minute they get into action.

The difference between *speedometers* is chiefly *under the skin.* Some devices carried on automobiles may *look* like *Stewart Speedometers,* but *users* find out the difference. The *Stewart* doesn't travel on its *looks* alone, but it travels on *four* cars out of *five* — and makes *good* on all of them.



It's the most *accurate* — the most *sturdy* — the most *reliable* speedometer made.

By *every* test it's far the *best.*

We manufacture on such a huge scale — our output is so tremendous — that the *Stewart* can be retailed for *less* than the production cost of the *rest.*

Magnetic principle — jewel bearings — wearing parts hardened and polished; open dial — big figures, easily read — absolutely accurate; 100,000-mile season odometer, 100-mile trip register, can be reset to any tenth of a mile. Guaranteed for five years. Strongest flexible shaft — drop forged swivel joint — noiseless gears.

New Chalmers "30" Roadster—$1400

A stylish, snappy, two-passenger torpedo roadster, with Chalmers self-starter, handsome top, windshield, tire-irons, quick-detachable 34 x 3 1-2 in. tires, cellular radiator, nickel trimmings, body finished in blue, hood and chassis black.

THE CHALMERS "30" Torpedo Roadster is designed for those who want a graceful, speedy, comfortable two-passenger car at a low price. It has all the features any one could desire in a car of this type.

This car has the Chalmers Self-starter—efficient, reliable, and simple. No cranking. No bother. No danger.

The seat is generously wide for two persons and is enclosed with wide torpedo doors. Gear shift and brake levers are inside the body. The body is low hung to give greatest riding ease.

The close-fitting top is of brown duck, making a very pleasant combination with the colors of the rest of the car. Side curtains and storm front go with the top.

Lamps, door handles, and metal parts of wind shield are black enameled with nickel trimmings. Other bright metal parts of car, such as steering column, bonnet hinges, running board ledge, are nickel-plated.

The roadster has beauty of line—perfect symmetry. It is handsomely finished, the body is painted an attractive blue with black mouldings. Hood and chassis, including wheels, are black with blue striping.

The gasoline tank is large enough so that it will only require refilling about once a week in ordinary driving. It holds 35 gallons, and is enameled black to harmonize with the chassis.

A Car for Men Who Do Things

There are no limits to the practical uses of the Chalmers "30" Torpedo Roadster. This car meets every demand of the man to whom being in the right place at the right time means everything.

The physician, the contractor, the real estate man, the salesman, the manufacturer—in fact, any one to whom time is money—will find this car a willing, efficient assistant.

The man who lives out of town, or whose business takes him to near-by towns frequently, finds a Chalmers roadster most convenient. He is independent of train schedules.

Think how much more you could accomplish in a day with less effort than you now spend if you owned one of these cars. It takes less than one-third as long to get around in an automobile as in a street car.

If you already have a touring car you can multiply by two the efficiency of your motor-car service by using the Chalmers roadster.

Buy a Car That Will Last

The Chalmers Roadster is a real car—not a toy. It is solidly built—the kind of car to stand up under hard usage and bad weather. It has the looks and finish of a high-priced car.

It has the same mechanical features which have demonstrated their efficiency in other models of the famous Chalmers "30."

The price of $1400 includes complete equipment—Chalmers self-starter, magneto, dual ignition, Prest-O-Lite tank, gas lamps and oil lamps, top and automatic wind shield, tire irons, horn, tire inflater, pump, jack, full set of tools, and tire repair outfit.

Call and see this Torpedo Roadster at our dealer's. There you can see for yourself how good it is.

Orders for this car should be placed at once to insure delivery this season. Only a limited number of "30" roadsters are being built, and the demand is sure to exceed this number.

Chalmers Motor Company, Detroit, Mich.

Performance the Mighty Factor Behind the Success of Fisk Tires Heavy Car Type

THEIR rapidly increasing sale is due to the verdict of the car owners who, once using them, buy again for their own cars and recommend them to their friends. "You are urged to inquire among Fisk Tire users" because we can present no stronger argument than the everyday service Fisk Equipment is giving. MILEAGE AND DIRECT REPRESENTATION combine to make the only service that really interests any buyer. It is *that* SERVICE upon which the success of Fisk Tires is founded.

Two New Anti-Skid Tires

Bailey Tread

Heavy buttons and one more row than any other Bailey Tread on the market. This increases the anti-skid surface and length of service as outside rows of buttons give anti-skid protection when center tread is worn down. These buttons are additional to the regular thickness of the smooth tread tire.

Town Car Tread

This provides a heavy anti-skid tread designed to insure traction and afford the greatest possible protection against skidding. It is positive in action on city pavements and country roads, and eliminates the necessity of chains with the attendant expense, noise and inconvenience.

Fisk Heavy Car Type Tires Are Sold by All Prominent Dealers

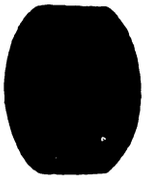
ELEVEN FACTS ABOUT HYATT ROLLER BEARINGS

1st

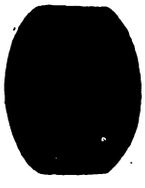


Hyatt Roller Bearings afford a line (—) bearing instead of a point (.) bearing as is the case with ball bearings. There is more surface to carry the load, yet with but little friction. They are American bearings for American roads.

2nd

Hyatt Roller Bearings are flexible. They give under shock, still are rigid enough to carry their load and remain round.

3rd

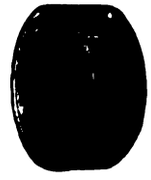


Hyatt Roller Bearings are Quiet. Noise is caused by the vibratory motion of any solid substance. Shocks and jars produce vibrations which rigid bearings transmit and intensify. The flexibility of the Hyatt Roller cushions shocks—absorbs vibrations—hence reduces noise.

4th

Hyatt Roller Bearings will retain a large quantity of Lubricant because the rollers are hollow. The spirals in the rollers alternate from right to left, thus constantly distributing the lubricant in all directions over the surface of the rollers.

5th

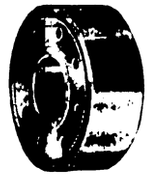


Hyatt Roller Bearings have No delicate Adjustments to be tampered with after the car has left the factory. Carelessness, curiosity or ignorance will not cause trouble by making improper adjustments in Hyatt Bearings as is often the case with others.

6th

Hyatt Roller Bearings are less liable to Accident or Injury because they carry the same load on a larger surface than ball bearings afford.

7th



Hyatt Rollers Never Crowd or pile up in a bearing, thereby grinding and destroying the entire bearing.

8th

Hyatt Rollers Will Not Crack or split as balls sometimes do when the wheels drop into a rut and the car is heavily loaded, thus causing annoyance, delays and expensive repairs.

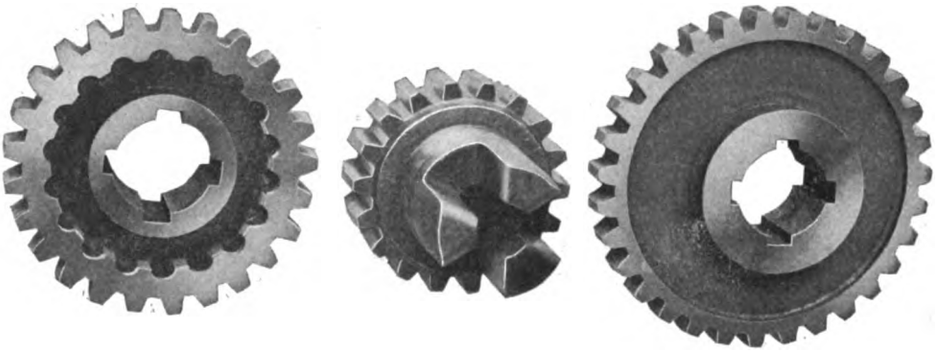
9th

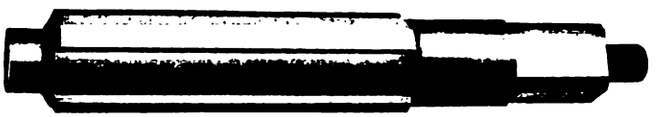
Hyatt Roller Bearings Reduce excessive and unnecessary Wear because they relieve gears and shafts of undue strains resulting from imperfect alignment.

10th

Hyatt Roller Bearings are made only from carefully Selected Steels which are chemically and physically tested, hardened and ground.

11th





Hyatt Roller Bearings will be used on 91.7% of all pleasure and commercial cars that will be manufactured during the season of 1912.

The Comprehensive Regal Line

$1400
MODEL "H"

The Regal "35" Underslung Touring Car

A COMPREHENSIVE LINE is the natural business getting Line for any dealer to handle. By comprehensive, we mean a line of automobiles that are distinctive in design—advanced in construction, high in quality in comparison—and lowest in price by all fixed standards as automobile values are classified today. We affirm the Regal line of cars to be nearer this dealer's ideal proposition than any line we happen to know of.

IT IS GOOD BUSINESS POLICY for the dealer to be able to meet any or all demands that may be made for certain types and certain prices by prospective purchasers of automobiles. Just because you happen to represent a car that doesn't meet the necessities of a man's pocket-book or his pre-conceived conception of about the kind of car he wants, it hurts to see him go up or down the street and buy elsewhere—besides, it's a poor business organization that can't meet competition.

THERE ARE A LOT OF MEN in your town or community who have set their hearts upon a Roadster. They don't want to pay a fancy price. They want a Roadster that is built a Roadster from the ground up. No Roadster body on a touring car Chassis for them. They desire a car that not only is a Roadster, looks like a Roadster, with power and speed enough to act like a Roadster, but is also a reasonable price. It is just because the Regal "25" Underslung Roadster at $900 is the most beautiful, most advanced in Roadster construction and the lowest-priced Roadster, quality considered, upon the market, that we sold more Roadsters last year than any other maker in the business—We should say, Regal dealers sold them.

YOU ALSO KNOW of a number of people who have decided that they can afford a Touring Car (if it meets their ideas of a good car) around $1000. Lucky the dealer who sells such a car because he has before him a certainty of big business for 1912. But a "25" horse-powered "Underslung" Touring Car at $950 with 106 inch wheel base and all the Chassis and body equipment of cars selling at double the price, is a business asset that even in this day of stiff competition is worth talking about. Our competitors frankly acknowledged at the New York and Chicago shows that this new Regal hadn't any competition. The answer for any dealer is "I can sell more of these Regal Cars in 1912 than I have ever sold of any make of cars since I have been in business."

AMONG YOUR PROSPECTS are also a number of doctors and business men to whom you can sell Coupes. This is a type of car that has become exceedingly popular, because it meets weather inclemency and gives a lot of all year 'round comfort. You've seen the Regal "25" Underslung Colonial Coupe at $1250. You couldn't help it because it is the most distinctively beautiful Coupe in the country and we're not bragging either. You've secretly admired it and tried to compare it with other Coupes. But you can't find a true comparison for this car. Ever since it made its appearance our dealers have kept us busy filling orders. It's a car that sells itself. No man who was in the market for a Coupe and saw this Regal Underslung ever went any further to see another. Besides, for $150 extra he could buy a Roadster body and he had a car for any season. Surely, there is a moral here for any dealer.

THEN, ALONG COMES THE MAN who wants a car around $1400. There's a Regal Underslung for him, too. We call it Model "H," our "35" H. P. Touring Car. The climax of the Regal Comprehensive Line. A big, powerful, roomy, beautiful car that embodies the elements of safety, economy, accessibility, comfort and easy riding ability peculiar to the advanced "Underslung" construction. This was the first "Underslung" Touring Car built to sell for less than $4,000. The car that gave an opportunity for men of moderate incomes to enjoy the advantages of this costly construction. Here are a few of its generous specifications: Motor, 35 H. P. 4 cylinders (in pairs) 4¼ x 4½; Wheel base, 118 inches; Morgan & Wright tires 34 x 4; Demountable rims (one extra free of charge); three speeds and reverse. Hyatt nickel steel roller bearings. Dual ignition with magneto. Standard equipment, etc.

WE'VE PRESENTED OUR CASE—Here are cars that meet the demand of the majority of people who buy automobiles. They also have these advantages. They are all "Underslungs." Any engineer will tell you Underslung construction is the eventual construction. They present a range of Models to suit every taste and need. What is most important—any one of these cars presents more in quality at a less cost to the purchaser than any car we know of. For instance, where can a man buy a "25" H. P. Underslung Touring Car for $950? The Regal Line is a big business asset for any dealer.

A Straight side or Clincher Tire fits the same STANDARD UNIVERSAL RIM

THE REMOVABLE RIM flanges are simply reversed—they curve outward on one side to fit a straight side tire, inward on the other to accommodate a clincher.

The Automobile Manufacturer should equip his cars with STANDARD UNIVERSAL RIMS. He removes another obstacle from the highway of increased sales. The automobile enthusiast demanding any style of tires can be satisfied by merely the change of casings.

The Tire Maker should welcome STANDARD UNIVERSAL RIMS, knowing that any style of tire, whether straight side or clincher, will fit this universal rim. He sells the style that he desires to push.

The Auto Buyer should demand STANDARD UNIVERSAL RIMS. He has an unlimited tire field from which to make his selections—any type—any style.

STANDARD UNIVERSAL QUICK DETACHABLE DEMOUNTABLE RIMS—Two turns locks in place and two turns unlocks for demounting. Send for Catalogue No. 607.

Self Hanna Starter

Back of every Starter we sell is an unlimited guarantee.

The fact that we charge only $10.00 for the Valentine Self-starter and Gas Lighter does not mean that it is a cheap starter—it means only that $10.00 is enough for a man to pay for a manifold starter.

The first acetylene starter on the market. The only 100 per cent. efficient self starter.

Hanna Self-starter, such a thing as failing to start is unknown. Nor will the Hanna Self-starter soot or foul your plugs in any way, shape or manner. The Hanna Self-starter was the first acetylene self-starter on the market—but it was never pushed until it had reached its present perfected state—that is how the Hanna Self-starter is able unqualifiedly to guarantee its operation and construction. And its guarantee is not limited in any way.

We guarantee the Valentine Self-starter to do just what we claim for it and when we sell it, we stand ready to refund the money if the purchaser is not thoroughly satisfied with it. All of our dealers are authorized to make this same proposition and we stand back of them.

Of course, we guarantee the Hanna Self-starter to be absolutely 100 per cent. efficient—with the

No manifold starter at any price is better than this at

$10

By becoming our representatives, dealers are taking on the best line for themselves. If your customer wants a low priced manifold starter, sell him the Valentine for $10.00; if he wants the superior of all other starters, the only 100 per cent efficient self-starter, sell him the Hanna Self-starter at $35.00. If he buys the Valentine and later wants the Hanna, allow him full price for the Valentine.

Carry this line and you never lose a self-starter sale.

Franklin D Touring

The big brother of the "Little Six"—a light weight, full size, five-passenger car, comfortable, speedy and economical.

Ability to Make Speed With Comfort

Makes Franklin model D the fastest touring car over the road. It is the first in at the end of the day's run and the occupants are not tired out.

Here Are the Specifications

Two types, a five-passenger touring car or a four-passenger torpedo-phaeton—six cylinders, thirty-eight horse-power.

Wheel base is 123 inches.

Full-elliptic springs and a wood frame—road shocks are absorbed.

Sheet aluminum body—light weight and will not rust, check or crack.

Tires 36 by 4½ inches front, 37 by 5 inches rear—larger than on any other car of the same size.

Price, $3500 for either type.

Light Weight on Large Tires—Low Tire Cost

Model D is a light weight car—and extra large tires are used.

It wears out fewer tires than any other car of its size because they are not overloaded.

Service averages from 8,000 to 10,000 miles per set.

Tire cost is reduced two-thirds.

A Safe Car to Drive

To drive a model D is a pleasure without fatigue to the driver or to the occupants.

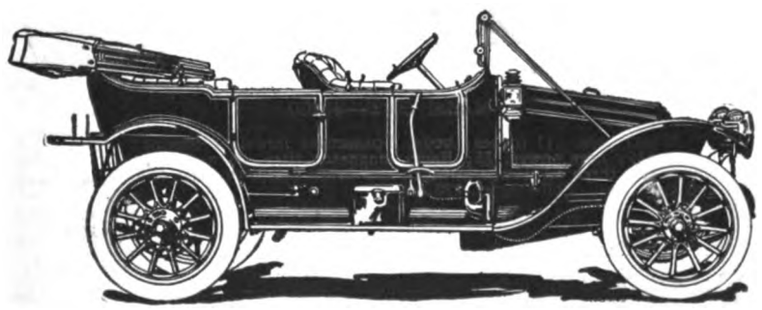
It goes the farthest and the fastest in a day because it is the safest and most comfortable.

It runs longer and faster and makes more miles and more trips without mechanical troubles than any other car.

It follows the road easily—steering is without effort.

Franklin Air Cooling

In the Franklin system of air cooling the suction fan fly wheel regulates the amount of cooling.



The faster the motor runs the greater the amount of air drawn around the cylinders.

Cooling does not depend upon the forward rush of the car, nor on a supply of water, nor on outside temperature.

As long as the motor runs it must cool.

The heat is literally wiped away—the supply of cooling medium never gives out.

Write for catalogue of all models.

THE MOTOR WORLD

Vol. XXXI New York, U. S. A., Thursday, April 25, 1912. No. 5

DARK HEAD OF ELECTRIC PROJECT

Election of Officers Discloses Strong Men Engaged in Buffalo Merger—Merged Companies Not Yet Uncovered.

Having completed its preliminary arrangements, the Buffalo Electric Vehicle Co., which was incorporated last month, under New York laws, with $1,000,000 capital, elected officers on Monday last, 22nd inst., its personnel, as then disclosed, making plain that the enterprise would not lack substantial and influential backing.

The officers are as follows: President, Samuel J. Dark; vice-presidents, A. A. Landon and W. A. Morgan; treasurer, Harry Yates; secretary, Alfred W. Thorn. The directors of the company are Messrs. Dark, Landon, Morgan and J. T. Steele and John W. Van Allen.

President Dark is secretary of the Buffalo Dredging Co., secretary of the German-Bock Asphalt Co. and a director of the Commonwealth Trust Co.; Vice-president Landon is superintendent of manufacture of the American Radiator Co. and president of the Clark Motor Co.; Vice-president Morgan is district manager for Swift & Co., president of the Buffalo Taxi Co. and a director in the Buffalo Copper & Brass Rolling Mill; Treasurer Yates is first vice-president of the Union Furnace Co., treasurer of the Lafayette Hotel Co. and vice-president of the Commonwealth Trust Co.; Secretary Thorn is president of the Thorn Cement Co. and a director in the Commonwealth Trust Co. Director Allen is an investment broker and Director Van Allen a prominent Buffalo attorney.

The company represents a merger of five Buffalo concerns and will manufacture electric vehicles of all types.

Dorman Becomes Steinbock's President.

Frank D. Dorman, secretary of the United States Motor Co., has resigned that office to accept the presidency of the Steinbock Engineering Co., of Peekskill, N. Y., which recently was organized by H. E. Steinbock, who at one time was chief designer for the Maxwell-Briscoe Motor Co. Dorman's identification with the industry dates back to 1903, when he organized the American Motor Carriage Co., of Cleveland, Ohio. Three years later he became secretary of the Maxwell-Briscoe Co., subsequently becoming its vice-president, which office he occupied at the time it was taken over by the United States Motor Co. The Steinbock Engineering Co., as the Motor World previously stated, will manufacture a moderate priced car, designed by Steinbock, at a factory which will be located in New Jersey, in the vicinity of Newark. The experimental work has been completed in Mr. Steinbock's own shop in Peekskill, and the car probably will make its appearance before the summer has spent itself.

Can't Use Name "Krupp" in Any Form.

The Krupp Motors Co., of Pittsburgh, Pa., which planned to build a $600,000 automobile factory somewhere or other and which spurned, or said it spurned, the offer of a Chicago banking house to take over a bond issue of $5,000,000 if the company would create one, will have to find another name for itself. The injunction to that end, which was prayed for by Thomas Prosser, the American agent for the great Krupp Steel Works in Germany, was granted by the United States District Court last week. It restrains the Krupp Motors Co. from employing the name Krupp in any manner whatsoever. The company, which is said to have spurned $5,000,000 apparently thought so little of its name that it did not put in an answer and an appearance.

Studebaker Trademarks Name "Flanders."

The Studebaker Corporation has been granted a trademark on the name Flanders, as applied to automobiles, which, in view of reports that other interests had designs on that name, which has been current for some months, may or may not contain significance. Application for the trademark was filed on December 18 last, as applying to the name Flanders in a fancy script design.

LAMP LIGHTERS THREATEN TROUBLE

Barger Patent on Regulating Valve Brought to Bear and Litigation in Sight—May Affect Engine Starters.

After receiving notice from the Inst Lighter Co., of Columbus, Ohio, to cease infringement of its patent, No. 942,995, the Simkin Mfg. Co., of Chicago, makers of the Daisy lighter, made its peace to such good purpose that it not only agreed to recognize the validity of the Inst patent, but to pool issues with the Inst company and make common cause against other makers of automatic lighters and engine starters which employ pressure regulating valves.

The patent on the Simkin device has not yet been issued, but the Inst lighter, covered by patent No. 942,995, was granted December 14, 1909, to Frederick C. Barger, of Columbus, Ohio. It applies specifically to a "pressure controlling valve for automobile lamps" and in the description leading up to the single claim which constitutes the patent, the patentee states that it has "particular relation to a gas valve mechanism adapted to be used in conjunction with electrically ignited gas lamps of the class in which acetylene gas is conducted from a pressure tank to the lamp burners."

Unless the Simkin patent, which still is pending and the exact nature of which has not been disclosed, contains more far-reaching claims, it is not easy in the face of Barger's specific declarations to distinguish wherein his patent applies to engine starters. That it is the Inst-Simkin interests' purpose to proceed against manufacturers of the latter, however, is the assertion that comes directly from the parties interested.

The pressure-controlling valve covered by the Barger patent is thus described:

"In a pressure-controlling valve for automobile lamps, the combination with a valve casing body, having four externally threaded extensions thereon, there being a port extending between two of said extensions, a pair of separated valve seats located in

Digitized by Google

said port, a cut-off valve threaded into another of said extensions and engaging one of said valve seats, a packing nut threaded upon said extension, a controlling handle carried by said valve and extending through said packing nut, a regulating valve threaded into the remaining one of said extensions and a packing nut through which said regulating valve extends, said packing nut being threaded upon the remaining one of said extensions, both the regulating valve and the cut-off valve being accessible and controllable from the exterior of the valve casing."

Expansion of the Wasson Piston Ring.

Its concentric piston having met with a remarkable measure of success, the Wasson Piston Ring Co. has increased its capital from $35,000 to $125,000 and removed from Bayonne, N. J., to a larger three-story plant at 1121-1123 Clinton street, Hoboken, where an output commensurate with the demand will be made possible. Coincident with the removal, Marshall F. Mills will become manager of the company, succeeding L. B. Berstein, who, however, retains his holdings in the company. The other officers are R. B. Wasson, president; E. R. Hewitt, vice-president, and M. L. Dunham, secretary-treasurer. Although not a great deal has been said of it, the Wasson ring really has made a great progress and now is employed by a number of prominent auto manufacturers, who have wholly discarded the long familiar eccentric ring, from which the Wasson differs in that its thickness, instead of being greatest at a point opposite the joint whence it gradually tapers to about half the thickness where the ends come together is the same for its whole circumference. Consequently the ring fills the whole groove in the piston, leaving no space, as the eccentric ring does, for the accumulation of oil and soot. In order to give the Wasson rings the proper elasticity, they are cut and then peen-hammered inside, the result being that an equal pressure is exerted all around the cylinder.

Again Enlarging Franklin Factory.

Ground will be broken, probably this week, for an enlargement of the H. H. Franklin Mfg. Co.'s factory in Syracuse, N. Y., which will afford 30,000 square feet of additional floor space. The new structure, 200x150 feet, will adjoin the present main factory building and will be devoted chiefly to the production of sundry parts and thus relieve congestion which has resulted from the increase in the Franklin business.

Gets Bosch Products For All Canada.

The Canadian Fairbanks-Morse Co., Ltd., of Toronto, has been appointed distributer of the Bosch magneto and other Bosch products for the entire Dominion. In addition to the main office in Toronto, the Fairbanks-Morse Co. maintains branches in eight other cities.

LAMBERT PLANT IN LOS ANGELES

Ohio Manufacturers Decide to Build on Pacific Coast—Will Produce Only Friction-Drive Farm Tractors.

Following a careful personal inspection of the field by J. W. Lambert, treasurer and general manager of the Buckeye Mfg. Co., of Anderson, Ind., the interests represented in that company are making ready to establish a factory in Los Angeles, or in the vicinity thereof. The Pacific Coast plant, however, will not produce Lambert cars or trucks, but will be devoted exclusively to the manufacture of the Lambert orchard and farm tractors, which recently have been developed at the Buckeye factory in Anderson, and for which a ready market has been found on the Pacific Coast. They incorporate the friction drive, which is the chief feature of the Lambert cars.

The four members of the Lambert family who control the Buckeye Mfg. Co., and who are its officers, will retain the controlling interest in the Los Angeles project, which, however, will be operated as a separate enterprise.

J. W. Lambert, who spent some time on the coast before a decision was reached, will shuttle between Indiana and California after the tractor factory is in operation and thus keep an eye on both properties. He is at present in California seeking the necessary factory site.

Why One "Star" Salesman is Missing.

Not so many weeks ago the Penfield Shock Absorber Co., of Meriden, Conn., acquired a "star" salesman who gave his name as Burton L. Burr, and proved of such engaging personality and so full of self-confidence that he offered to work on a commission basis in order to prove his worth. The Penfield people made terms with him, and Salesman Burr took to the road and in no time at all turned in whole sheafs of orders on which he duly collected his commission. Also in due course the Penfield company shipped the orders and suspected nothing until those to whom the goods were consigned refused to accept them and reported either that they had not seen Mr. Burr or had placed no orders with him. When Burr was called on to explain matters, he deemed it the better part of wisdom to disappear. At last accounts, he was still missing.

Jeffery-Dewitt Plans Ten Million Plugs.

Ten million spark plugs per year will be the capacity of the Jeffery-Dewitt Co. when the enlargement of its plant in Detroit, which now is in progress, is completed. The enlargement comprises a brick building 100x400 feet, which will be finished within thirty days. It will be devoted entirely to potteries for the porcelain for the J-D spark plugs—which are made from clay and other ingredients which are brought from Europe—and will permit of an output of 36,000 porcelains a day, which is at the rate of 10,800,000 per year.

Froelichs Enter the Tire Trade.

Jesse Froelich, who recently resigned the management of the Benz Import Co., of New York, but who retains his interest in the company and also in the Times Square Automobile Co., has organized the Mecca Rubber Co. which, about May 1st, will be ready for business at Broadway and 54th street, where it will act as Eastern distributors of Imperial tires. The company has not yet been incorporated, but Jesse Froelich will be its president, Morris Froelich its vice-president, and Louis Mensbach its treasurer.

Chicago Abandons Fall Truck Show.

The Chicago Automobile Trade Association has abandoned the truck show which it proposed to hold in the Coliseum next fall, and, it is announced, will withdraw its application for a sanction which had been filed with the National Association of Automobile Manufacturers. The action of the Chicago association was undoubtedly due to the fact that the N. A. A. M. had conveyed the intimation that it did not view with favor the proposed show.

Franklin Departs to Pacific Coast.

H. H. Franklin, president of the H. H. Franklin Manufacturing Co., of Syracuse, N. Y., departed last week for his annual visit to the Franklin branches and Franklin agents in the more populous centers. His itinerary includes Cleveland, Cincinnati, Chicago, Salt Lake City, Los Angeles, San Diego, San Francisco, Portland, Seattle, Spokane, Helena, St. Paul and Milwaukee.

Pope to Erect Four-Story Addition.

The Pope Manufacturing Co. is about to place contracts for a large addition to its plants in Hartford, Conn., which will be completed on or about September 1st next. The new building will be a four-story brick structure 192x72 feet. It will afford facilities neceessary for the production of the moderate-priced car which will be added to the Pope line next year.

Albion Plant a Hayes Subsidiary.

Mark Merriman, vice-president of the Hayes Wheel Co., of Jackson, Mich., who was reported to have purchased a plant in Albion, Mich., for the purpose of producing metal parts for automobile wheels, will not operate the factory on his own account. The Albion enterprise will be a subsidiary of the Hayes Wheel Co. itself.

Chalmers Swings Around Trade Circle.

Hugh Chalmers, president of the Chalmers Motor Co., of Detroit, is making a wide swing around the trade circuit. Among others he is visiting all the more prominent Pacific Coast cities, his trip reaching as far as Vancouver.

BIG CORPORATION'S PROFIT-SHARING

United States Rubber Co. Makes Public Plan Finally Adopted—Bonus is Offered for Satisfactory Service.

After considering the subject for some three months, the United States Rubber Co., of which the United States Tire Co. is a subsidiary, finally has made known the plan whereby its employes will be permitted to share in the profits of the $100,000,000 company. It includes the distribution of common stock at $45 a share among all employes receiving a salary of $1,300 a year or over, subscriptions to be paid for in installments of not less than $4 per share a month. The plan will be followed out, if it is successful, in succeeding years, although the present market price of the stock, about $56 per share, will not, of necessity, remain in force.

In the words of Samuel P. Colt, president of the big company, the profit-sharing is designed "to further development of the interest, loyalty and efficiency of the salaried men in its service, and in that of its subsidiary companies, by giving them a special motive for acquiring or retaining an interest in the company's stock so as to make them substantially partners in the enterprise."

"For this purpose the company acquired in the market a large number of shares of its common stock at $45 per share, and is now offering it to its employes at this figure," continued Mr. Colt, "and the offer is limited to those receiving $1,300 a year and upward on the idea that they will best be able to meet the required payments of $4 per share per month without taking any undue financial burden.

"To make the privilege for subscribing at $45 still more attractive and also to make it the more probable that subscribers will retain their stock and so retain their interest in the company's welfare; it is proposed to give them a cash payment of $3 per share for each of the coming five years, provided subscribers retain their stock during that period and obtain a certificate at the end of each year that their services have been satisfactory to the company.

"To make the payments on the subscriptions less burdensome to subscribers, the company will distribute a certain profit-sharing fund among them. Any subscriber may, until it is fully paid, cancel his subscription at any time, and in that case, will be refunded all he has paid, together with interest of 5%. In case of the death of a subscriber during the five years, his family will receive the same benefit he would have received under these plans had he lived. Any fortfeiture caused by unsatisfactory services, or by termination of services, will inure to the benefit of the other subscribers."

If the plan works out successfully it is intended to make a similar offer in each suceeding year, the price of such future subscriptions, however, to be determined partly by the then prevailing market price of the stock and other existing conditions.

Henry Car "Gives up the Ghost."

Efforts to reorganize the bankrupt Henry Motor Car Co., of Muskegon, Mich., have proved vain and the business will be discontinued. The bid of C. E. Latimer, the heaviest stockholder in the company, did not avail, a higher offer made by Philadelphia parties for the cars on hand and other assets being accepted. The good will and repair business were purchased by the Muskegon Auto Co., with which A. R. Palmer, former president of the Henry company, is connected. It will keep on hand a supply of spare parts for Henry cars and promises prompt delivery thereof.

Body Builders Will Get Their Money.

The Moore & Munger Co., the New York body builders, were last week awarded the full amount of their claim against Wyckoff, Church & Partridge for the value of three bodies at $997 each, which the Wyckoff concern had ordered and refused to accept, despite the fact that it supplied the three chassis to which the bodies were to be fitted. The New York Supreme Court, which rendered the judgment, has ordered the chassis and bodies sold on Saturday next to satisfy the claim of the plaintiff in the action.

Vanguard Increases and Seeks New Site.

The Vanguard Mfg. Co., of Joliet, Ill., has increased its capital stock from $25,000 to $50,000, and its number of directors from three to five. The two new directors are W. H. Whitmore and William Thoeming; the old ones are C. F. Jensen, Edward Steinhart and Nathaniel Hurd. The added capital will be used in purchasing a newer and larger factory for the manufacture of Vanguard windshields, and it may or may not be located in Joliet.

Miller Carburetter Locates in Indiana.

Despite reports that it would locate in Detroit, Pittsburgh and elsewhere, the Miller Carbureter Co., of Los Angeles, finally has taken up its abode in Indianapolis, where temporary quarters have been secured in the Murphy Building. S. G. VanCamp, of the VanCamp Hardware Co., of Indianapolis, is interested in the carburetter company and was instrumental in inducing it to locate in the Indiana metropolis.

Fowler Takes Over Carburetter Plant.

The Fowler Lamp & Brass Co., of Chicago, Ill., which recently acquired the Roberts Brass Mfg. Co., of that city, has also taken over the Reisenbach Laboratories Co., manufacturers of Vortex carburetters, and the entire business has been concentrated in the Fowler Building on East 24th street, Chicago. The facilities of the several departments will be considerably enlarged.

"TRADE TALK" NOT VALID EXCUSE

Michigan Court Rules on Claims Made by Salesmen and Indicates Responsibility —Litigation Over Trucks.

In Michigan so many cars are made and so many people are making them and selling them, by methods high sounding and otherwise, that the decision of the Supreme Court of the State recently rendered in the case of Hall vs. Duplex-Power Car Co. cannot fail to give pause to those who are more or less inclined to the use of extravagant claims and phrases in advertising or otherwise prosecuting the sale of their wares. The case in question, Eugene H. Hall, of Kansas City, Mo., late in 1909 secured the sales agency for the Duplex four-wheel drive truck, placing an order for three vehicles with their makers, the Duplex-Power Car Co., of Charlotte, Eaton County, Mich.

The vehicles were duly delivered, but failed to stand up and were accordingly returned to their manufacturers and a demand made for a settlement, which was refused. The Kansas City man then entered suit in the Circuit Court for Eaton County, Mich., claiming fraud and deceit and breach of an implied warranty. After hearing the evidence, which included testimony of Morris Bollstrom, the inventor of the Duplex drive, to the effect that the vehicles delivered to Hall were undeveloped and unsatisfactory and were shipped contrary to his protest, the court directed a verdict for the defendant. Hall, however, appealed from the decision and the higher court just has reversed the "court below" and ordered a new trial, holding (1) That the undertaking of the defendant to replace all defective parts constituted an express warranty and there could be no implied warranty as to the workmanship and proper assembling of the machines. (2) That defendant's oral representations as to tests made, what the cars would do, the class of workmanship and materials used made a question for the jury upon the question of fraud and deceit, and it was an error to direct verdict.

"Where, in a contract for the manufacture of machines there is an express warranty that all the machines shall be like the sample, no other warranty can be implied," said the court, which also added:

"One who purchases property in the belief of, and reliance upon, false statements regarding it, may sue for and recover the damages occasioned thereby, whether the representations are made in good or bad faith."

One of the exhibits which the plaintiff brought to bear was the advertising literature of the Duplex company. Among other things it dealt with the Duplex vehicles in this florid, but not uncommon, fashion:

"You can pay more, but you cannot buy another delivery in America that can be

Digitized by Google

depended upon to run the year 'round through mud, slush and snow."

"This car will do more work than two horse drawn rigs; with one less driver, costs less to maintain; quicker deliveries, well pleased customers. More of them."

"A ten passenger bus that you won't have to leave in the garage because of the mud or snow. Artillery wheels if you prefer them."

"This is the 1,000 lb. capacity car that beat two double teams 4½ hours in a day's laundry delivery. Making a total of 115 miles on 9½ gallons of gasolene."

"Not a car offered for sale until they had made good on every kind of road in this country and they never flunked."

"Remember these cars are not assembled jobs, simply put up to sell to people who do not know the difference, but they are manufactured in our own plant where nothing but commercial cars are built, by men who gave their entire time and thought to the construction of the best commercial cars ever produced in America."

Hall testified that F. A. Messler, the secretary of the Duplex company, talked along these same lines—told of the "great stunts" the trucks performed, of their surpassing quality and workmanship, etc., and though the defendant's lawyer tried to dismiss such assertions as "trade talk not amounting to material representations relied on by the plaintiff," the higher court, in dealing with that phase, said:

"Bearing in mind the nature of the representations testified to, and the entire inexperience of the plaintiffs in handling automobiles of this or any other kind, and the testimony tending to show the falsity of the representations, we must hold that there was sufficient evidence introduced in support of the count for fraud and deceit, to entitle the plaintiff to go to the jury upon this question. If it is a fact that these statements were made and relied upon by the plaintiffs, and induced plaintiffs to enter into the contract, and were false in fact, it is immaterial whether Mr. Messler believed them true."

Lamp Meeting That Threw No Light.

If the New York correspondent of the Cincinnati Enquirer is to be believed, a meeting was held in a prominent Broadway hotel one day last week, at which interests representing the United States Motor Co., the General Motors Co. and the Studebaker Corporation, took steps toward the organization of still another company which will manufacture the lamps, if not other accessories, used by the several big corporations. If such a meeting was held, officials of the United States Motor Co., at least, know nothing about it. Alfred Reeves, one of the vice-presidents of the company, laughed heartily when it was repeated to him and suggested that it was merely another variation of the United States Motor-General Motors-Studebaker merger which has given rise to "newspaper dreams" on previous occasions.

STEARNS' VIEW OF THE SITUATION

Cleveland Company's Vice-President Surveys Business Conditions and Sees Few Clouds—What Orders Indicate.

When a man is ill, and more particularly when he is convalescing, he has time and opportunity for thoughts and surveys of situations for which he has less inclination, or less opportunity, when in full health and engaged in the rush of the work-a-day world. Roy F. York, vice-president of the F. B. Stearns Co., of Cleveland, Ohio, recently found himself in such a situation. He underwent an operation for a severe attack of appendicitis, and during his convalescence he devoted himself to an exhaustive study of business conditions in general and the automobile trade in particular. His opinions therefore are apt and of real interest.

"I closely analyzed the reports sent in by our branches, our dealers and our traveling supervisors," he said in remarking his conclusions, "and have gone very closely over the selling situation with the members of our sales committee, who direct the sales policy of the Stearns company.

"From all these sources and many others, I have come to the conclusion that the automobile business will not only finish the present season in flourishing condition, but will swing into the next season's business with more impetus than it has ever known before.

"These beliefs are not only based on the most careful study of the situation as a whole, but are conservative.

"I have gone over our own business in a more exhaustive manner, and I am proud to say that every branch and dealer on our books has shown a splendid increase. Probably the greatest increase of any is shown in New York. Since we organized the F. B. Stearns Co., of New York, about a year ago, and installed our sales offices and service building, our sales have increased wonderfully. Not only that, but the entire country east of the Allegheneys has shown a most wonderful increase.

"This does not mean that the western territory is not also increasing, for it is giving splendid results, especially on the Pacific coast.

"Our business so far is approximately 100 per cent. over last season, when, of course, we did not have the advantage of the Knight type motor. This means that our branches and dealers are doing from 150 to 200 per cent. more business. I find that practically all the companies building cars of standard quality are reporting good conservative increases over previous seasons. Our sales supervisors, who are in close touch with trade conditions all over the United States, believe that practically all the companies manufacturing cars of the better quality are having splendid seasons.

"I attribute this not only to the splendid cars being built today, but to the general business health of the country. The very few sections of the country, where business is somewhat slow, are the rare exceptions."

Indianans Take up a Tire Filler.

The Indiana Tire Filler Co., which just has been incorporated in that State with $25,000 capital, has located at 330 North Illinois street, Indianapolis. The officers are as follows: R. C. Ellis, New Albany, Ind., president; F. F. Wiley, Edinburg, Ind., vice-president; F. T. Mitchell, Chicago, Ill., secretary and treasurer. In addition to the officers, the directors are H. H. Woodsmall, of Indianapolis, and C. W. MacReynolds, of Kokomo. The company will manufacture a liquid filling compound, styled "Rubberine," which is the discovery of a New Orleans chemist, and which is claimed to be "almost as resilient as air."

More Money in Pittsfield Spark Coil.

The Pittsfield Spark Coil Co., of Dalton, Mass., has increased its capital stock from $100,000 to $250,000 and will use the new capital for the purpose of installing new machinery and otherwise increasing its facilities for the manufacture of magnetos, coils, spark plugs, etc. At the meeting of the company, at which the increase of capital was voted, William P. Wood was elected president and Louis B. Hopkins treasurer, who, with Zenas Crane and Michael Casey, will constitute the board of directors.

St. Louis Tradesmen Select Their Leaders.

At the annual election of the St. Louis Automobile Manufacturers' and Dealers' Association, the following officers were chosen: President, Frank R. Tate; vice-president, W. C. Anderson; treasurer, Samuel Breadon; secretary, Robert E. Lee. The directors are H. B. Krenning, John H. Phillips, E. P. Rhodes, O. L. Halsey, C. Gratiot Cabanne and T. L. Houseman.

Michigan Welding Company Enlarges.

The Michigan Electric Welding Co., of Detroit, which recently absorbed the Detroit Electric Welding Co., has acquired the property in Detroit formerly occupied by the Universal Radiator Co. and is removing thereto. The property comprises three buildings and sufficient land on which another three-story concrete structure will be erected.

Latta Made U. S. Motor's Secretary.

L. A. Latta has been elected secretary of the United States Motor Co. to succeed Frank D. Dorman, who resigned the office to become president of the recently organized Steinbock Engineering Co. Previously Latta was secretary of the Maxwell-Briscoe Motor Co. so that he is not strange to his surroundings.

THE WEEK'S INCORPORATIONS

Detroit, Mich.—Republic Motors of Michigan, under Michigan laws, with $20,000 capital.

Gray, Me.—Gray Auto and Supply Co., under Maine laws, with $10,000 capital; to operate a garage.

Seattle, Wash.—Seattle Auto and Freight Co., under Washington laws, with $10,000 capital; to deal in automobiles.

Wilmington, Del.—Sanitary Service Co., under Delaware laws, with $10,000 capital; to deal in motor car attachments.

Windsor, Ont.—National Body Co., under Canadian laws, with $100,000 capital; to manufacture automobile bodies.

Vincennes, Ind.—Traction Appliance Co., under Indiana laws, with $35,000 capital; to manufacture motors. Corporators—F. C. Morgan, G. E. Henry, J. J. Risch.

Anderson, Ind.—R. S. Brown Co., under Indiana laws, with $2,000 capital; to deal in motor cars. Corporators—R. S. Brown, Robert L. Colding and others.

Chicago, Ill.—D. A. Bonitz Co., under Illinois laws, with $5,000 capital; to deal in tires, etc. Corporators—Thomas M. Benner, Frank P. Paterson and others.

Wilmington, Del.—Elastic Wheel Co., under Delaware laws, with $1,000,000 capital; to manufacture spring wheels. Corporators—S. C. Hatfield, G. W. Smith, I. Fogg.

Chicago, Ill.—Transcontinental Touring Club of America, under Illinois laws; to develop motor touring. Corporators—Enos A. Hates, Harry C. Drum, Marvin O. Bates.

Chicago, Ill.—Logan Square Garage Co., under Illinois laws, with $2,500 capital; to operate a garage. Corporators—Edward S. Thurtell, Alfred Thurtell, Horace G. Sweet.

New York, N. Y.—Dual Wheel Co., under New York laws with $300,000 capital; to manufacture automobile wheels, etc. Corporators—F. B. Cochran, A. Dow, C. W. Jewell.

Detroit, Mich.—Maxeff Electric Horn Co., under Michigan laws, with $15,000 capital; to manufacture motor vehicle horns. Corporators—Ard. E. Richard and others.

Salem, Mass.—Salem Oil and Grease Co., under Massachusetts laws, with $25,000 capital; to deal in lubricants. Corporators—A. H. Rowbotham, H. T. N. Smith and others.

New York, N. Y.—Tire Core Co., under New York laws, with $100,000 capital; to manufacture tires, rims, etc. Corporators—R. V. Stuart, P. J. O'Connell, H. P. Reader.

Chicago, Ill.—Columbus Livery Co., under Illinois laws, with $6,000 capital; to conduct a motor livery. Corporators—Charles F. Thomas, Louis Kummerow, Ernest H. C. Wegner.

Portland, Me.—Railway Storage Battery Car Co., under Maine laws, with $4,000,000 capital; to manufacture battery cars, etc. Corporators—C. E. Eaton, C. L. Croteau and others.

Chicago, Ill.—Mid-West Auto Supply Co., under Illinois laws, with $50,000 capital; to manufacture automobile supplies. Corporators—S. G. Camp, Clarence Joseph, B. H. Rifenbark.

Indianapolis, Ind.—Hampton Mfg. Co., under Indiana laws, with $5,000 capital; to manufacture automobile accessories. Corporators—S. B. Nussbaum, S. Allmann and W. Hampton.

Chicago, Ill.—Fred Allen Automobile Supply Co., under Illinois laws, with $10,000 capital; to deal in motor requisites. Corporators—W. E. Kaiser, F. L. Horton, Percival Steele.

Chicago, Ill.—Brazil Tire and Vulcanizing Co., under Illinois laws, with $5,000 capital; to deal in and repair tires. Corporators—B. H. Bellman, Richard Leseth, Edward Lansberg.

Superior, Wis.—Continental Truck Mfg. Co., under Wisconsin laws, with $50,000 capital; to manufacture motor trucks. Corporators—E. M. Anderson, J. S. Barnsdale and others.

St. Louis, Mo.—Pennsylvania Automobile Co., under Missouri laws, with $10,000 capital; to deal in motor cars. Corporators—William A. Fortner, Claude D. Fortran, George P. Burleigh.

Buffalo, N. Y.—South Buffalo Garage, Inc., under New York laws, with $10,000 capital; to operate a garage. Corporators—William Coatsworth, Leon R. Jenkins and Mary L. Coatsworth.

Indianapolis, Ind.—Scheidel-Thompson Mfg., Co., under Indiana laws, with $50,000 capital; to manufacture automobile parts. Corporators—George I. Schellig, Bert Thompson and others.

Utica, N. Y.—Buick Sales Co., under New York laws, with $5,000 capital; to deal in motor cars. Corporators—George Beatty, Arthur Beatty and Emma Beatty, all of 143 Park avenue.

Terre Haute, Ind.—Vigo Mfg. Co., under Indiana laws, with $25,000 capital; to manufacture auto parts. Corporators—J. R. Finkelstein, R. G. Jenckes, Jr., L. M. Eyke and W. M. Lewis.

Kansas City, Mo.—Stephens Motor Tire Co., under Missouri laws, with $5,000 capital; to manufacture and deal in motor car tires. Corporators—A. J. Stephens, William H. Hall, E. J. Short.

Rye, N. Y.—Motor Mail Transportation Co., under New York laws, with $60,000 capital; to conduct a mail delivery business. Corporators—J. J. Cassidy, H. G. Warnock, W. C. Prime, all of Brooklyn.

Columbus, Ohio—State Auto Sales Co., under Ohio laws, with $10,000 capital; to deal in motor cars. Corporators—Mark B. Mead, George F. Hammond, W. G. Fligle, B. S. Dorrance, B. R. Dorrance.

Indianapolis Ind.—Vixen Motor Co., under Indiana laws, with $12,000 capital; to manufacture motor cars. Corporators—F. C. Schmid, W. J. Harris, C. O. Van Horn, S. B. Lindley and D. K. Lindley.

Chicago, Ill.—Byam International Autotire Co., under Illinois laws, with $50,000 capital; to manufacture automobile tires and accessories. Corporators—W. W. Byam, E. C. Byam, W. A. Scott.

Cleveland, Ohio—Universal Lubricating Co., under Ohio laws, with $100,000 capital; to deal in oils and greases. Corporators—S. W. Scofield, C. B. Emery, C. B. Arthur, T. H. J. Williams, Jr., E. Dreher.

Jersey City, N. J.—Unique Vulcanizer Co., under New Jersey laws, with $50,000 capital; to do a general automobile business. Corporators—J. H. Hutten, J. P. Becker, U. C. Huber, E. R. Hussey.

New York, N. Y.—Auto Import and Specialty Co., under New York laws, with $15,000 capital; to deal in automobile supplies. Corporators—Leo Kahn, Edwin P. Weiss, Hans Gurlitt, all of 1777 Broadway.

Cincinnati, Ohio—K. D. Carburetter Co., under Ohio laws, with $5,000 capital; to manufacture automobile supplies. Corporators—C. A. Riemenschneider, Harry C. Cahn, E. L. Fraser, C. W. Shimmon.

Yonkers, N. Y.—Park Hill Auto Co., under New York laws, with $15,000 capital; to deal in motor vehicles. Corporators—Eris Drewitz, Emil Drewitz and Paul T. Ellenbogen, all of 336 New Main street.

Alexandria, Va.—Capital Garage and Service Co., under Virginia laws, with $125,000 capital; to operate a garage. Corporators—Louis T. Cowle, Joseph B. Chaplin, Eugene A. Jones, all of Washington, D. C.

Cleveland, Ohio—B. & B. Mfg. Co., under Ohio laws, with $35,000 capital; to deal in motor car parts and accessories. Corporators—W. E. Smith, R. L. Bacher, W. R. Bauman, L. C. Heinberger, I. T. Quick.

Roslyn, N. Y.—Roslyn Garage, Remsen

Digitized by Google

& Hewlitt, Inc., under New York laws, with $15,000 capital; to deal in motor cars and operate a garage. Corporators—Samuel L. Hewlitt, John F. Remsen and Nora H. Remsen.

Granville, N. D.—Nordmarken Mechanical Motor Co., under North Dakota laws, with $10,000 capital; to manufacture internal combustion motors. Corporators—C. A. Stubbins, O. M. Erickson, J. J. Muus, all of Granville.

Brooklyn, N. Y.—T. F. P. Co., under New York laws, with $1,000 capital; to deal in motor cars. Corporators—E. Mulder, 626 West 136th street; F. W. Olmstead, 569 Madison avenue; John R. Mulder, 1531 Broadway.

Detroit, Mich.—England Manufacturing Co., under Michigan laws, with $50,000 capital; to manufacture steel automobile bodies. Corporators—Fred England, John W. Foster, J. Albert Davis, all of Amesbury, Mass.

Brooklyn, N. Y.—Royal Auto Co., under New York laws, with $600 capital; to deal in motor cars. Corporators—Harry Baumann, 178 Hewes street; William Gerdes, 482 Franklin avenue; Abraham Levy, 53 Clark street.

Cleveland, Ohio—Guide Motor Lamp Mfg. Co., under Ohio laws, with $100,000 capital; to manufacture automobile accessories. Corporators—H. J. Monson, W. F. Persons, W. H. Bunce, J. D. Kauffman, W. L. Rose.

New York, N. Y.—Auto Holding Co., under New York laws, with $10,000 capital; to deal in motor cars. Corporators—Minor O. Russ, 1047 Stebbins avenue; Harry Edwards, 567 West 186th street; Alfred Bernstein, 3089 Broadway.

New York, N. Y.—Ohio Tire Co., under New York laws, with $500 capital; to deal in vehicle tires. Corporators—Samuel Kessel, 1405 Forty-second street, Brooklyn; Fanny Karpowitz and Max Karpowitz, both of 166 South Second street, Brooklyn.

New York, N. Y.—Auto Transportation and Sales Co., under New York laws, with $1,000 capital; to deal in motor vehicles. Corporators—Edward E. Manning, 734 Eighth avenue; William Lanasseadel, 966 Stebbins avenue; J. Martin Burke, 54 West 113th street.

New York, N. Y.—Long Island Truck Co., under New York laws, with $3,000 capital; to deal in motor vehicles. Corporators—William L. Woodhill, 132 Fourth street; Peter J. Fisher, 61 West Eighty-sixth street; Wilson J. Backman, 149 West Sixty-sixth street.

New York, N. Y.—Rubber-Aer Co., under New York Laws, with $25,000 capital; to manufacture automobile tires. Corporators—Daniel B. Crane, Jr., 4164 Brander street, Woodhaven; Ernest Lavoie, 113 Seventh avenue; Hugh M. Smith, 222 Clark street, Westfield, N. J.

Buffalo, N. Y.—Autoaro Pump Co., under New York laws, with $1,000 capital; to manufacture pumps, etc. Corporators—Walter W. Cohen, 403 Potomac avenue; Louis K. Schwartz, 210 West Seventy-sixth street, New York City; Michael M. Cohen, Mutual Life Bldg., Buffalo.

Changes Among Prominent Tradesmen.

F. J. Posta has been appointed sales manager for the Harder Auto Truck Co., of Chicago. Previously he was connected with the Kissel Motor Car Co.

George T. Homeier has been appointed superintendent of the Streator Motor Car Co., of Streator, Ill. Previously he was connected with the General Motors Co.

George B. Pieper has been appointed manager of the Remy Electric Co.'s branch in Boston, Mass. Pieper has been identified with the automobile trade in several capacities for many years.

Fred J. Urban has been appointed special representative for the Remy Electric Co. in the middle west. He will make his headquarters at the Chicago branch and that city, of course, and Detroit will be included in his territory.

A. A. Franklin, former advertising manager for the Haynes Automobile Co., of Kokomo, Ind., has become identified with the Apperson Bros. Automobile Co. of the same city. C. E. Stolte, former traffic manager at the Reo factory at Lansing, Mich., also has been added to the Apperson staff.

W. S. Jewell, at one time manager of the Franklin branch in New York and more recently with the Kelly Motor Truck Co., has been appointed eastern sales manager for the R-C-H Corporation. He will make his headquarters at the R-C-H branch in New York, at 1989 Broadway. Jewell succeeds R. J. Lacair, who recently resigned his position.

W. T. Reynolds, for the past three years manager of the Franklin branch in Pittsburgh, Pa., has been appointed sales manager for the Lippard-Stewart Motor Car Co., of Buffalo. Previous to his connection with the Franklin company, Reynolds was engaged in the automobile business on his own account in Philadelphia, where he operated the Rittenhouse Garage, which was a John Wanamaker enterprise.

Queer Garage Situation in Detroit.

Opposition to the erection or maintenance of public garages in residential neighborhoods is an old story, but the situation in which the Kales Realty Co., of Detroit, Mich., finds itself proves more than usually peculiar. It owned an 82-foot lot on Woodward Avenue Terrace, in Detroit, on which it desired to erect a garage, but the residents of the neighborhood promptly sued for an injunction, alleging that when that section of the city was platted restrictions were imposed that forbade the construction of such a building. The Realty company contended that the restrictions covered only the northerly 10 feet of the lot, if it covered any part of it, and as the locality is now a business district the restrictions had been nullified. The complainants, however, held that the restriction, by an old lease, covered the whole lot. After the long wrangle, the court ruled that a garage might be erected on the southerly 72 feet, but that not even a carriage driveway could be laid out on the restricted 10 feet, so that the Realty company is, figuratively, "up against it," with a 10-foot waste on its hands. It claims that the court's decision renders the lot useless and has announced its intention of carrying the case to the Supreme Court of the State of Michigan.

Detroit Prepares To Receive S. A. E.

Detroit having been awarded the midsummer meeting of the Society of Automobile Engineers, and having set June 27, 28 and 29 as the dates, now is planning to receive and entertain its guests in a manner befitting the "automobile capital of the world." Hotel Pontchartrain has been designated official headquarters and the place for the several business meetings, the remaining details being in the hands of the following committees:

Entertainment—H. E. Coffin (chairman), Hudson Motor Car Co.; H. W. Alden, Timken-Detroit Axle Co., and Russell Huff, Packard Motor Car Co. Finance—H. M. Leland (chairman), Cadillac Motor Car Co., and Tracy Lyon, General Motors Co. Transportation—F. H. Floyd (chairman), E. E. Sweet, Cadillac Motor Car Co., and H. R. Corse, Lumen Bearing Co. Hotels—G. W. Dunham (chairman), Chalmers Motor Co.; F. H. Berger, Oakland Motor Car Co., and J. G. Vincent, Hudson Motor Car Co.

Peerless Floats Million Dollar Issue.

Chiefly for the purpose of its truck department and to pay off its floating debt, the Peerless Motor Car Co., of Cleveland, has floated an issue of $1,000,000 6 per cent. bonds, maturing in 12 months, the entire issue having been taken by a local banking syndicate. The company also has added $300,000 to its capital stock.

Fisk Completes New Home in 'Frisco.

The Fisk Rubber Co. last wek took possession of the new branch in San Francisco, which was erected for its occupancy. It is located on Van Ness avenue, near Pine street, and comprises a two-story reinforced concrete structure, 50x150 feet, and is characterized by uncommonly handsome appointments.

Croxton to Remove from Cleveland.

The Croxton Motor Co., of Cleveland, has completed negotiations which will result in its removal to Washington, Pa. The new plant secured at that point will enable the Croxton people to better carry out the plans which they have made for the future conduct of their business.

NEW YORK, APRIL 25, 1912.

ENGINE STARTERS AND ADVERTISING FOR TRUCKS.

It would seem that pleasure car manufacturers have sort of stolen a march on a majority of the commercial vehicle makers in so readily taking up the engine starter. There can be no doubt but that the engine starter is a boon and a blessing on a pleasure car, even though the number of times it may be called upon are comparatively few. But a motor truck is quite another proposition. The nature of its work generally is such that frequent stops for discharging merchandise are necessary. Inasmuch as it is perfectly apparent that an idle truck is a drain on resources and that an idle truck with its engine running as well, eating up gasolene and oil, must be a greater drain, it would seem that there are abundant possibilities for the engine starter in the commercial vehicle field.

A few manufacturers already equip their trucks with engine starters but the majority of them still rely upon the muscle of the driver, and it might be said in passing, that there are not many drivers who are prone to exercise their muscle a couple of hundred times a day in the particular manner that is suggested by an idle engine. At the least, an engine starter would encourage the driver to stop his engine when he stopped the vehicle to make deliveries, and even if it did not pay for itself immediately in gasolene and oil and wear and tear saved, it certainly ought to return dividends on the investment.

In this respect the electric engine starting and lighting system suggests itself as particularly applicable to commercial vehicles. In its various forms, as it is manufactured today, it does not require attention that is worth mentioning, it is not unnecessarily complicated, and its most valuable feature is a practically unlimited source of current that may be put to a variety of uses. And not the least valuable of the uses to which the current may be put is in advertising.

Admittedly, some of the very best advertising is accomplished with the aid of electric signs. With an electric engine starting and lighting system installed on a commercial vehicle, the owner is afforded an unsurpassed advertising medium in the electric signs which he may, with little labor or expense, attach to the sides of the truck body. Not only would the signs attract and hold attention when the truck is idle, but they would be carried far and near, spreading whatever gospel the owner might elect. The maintenance expense of such an outfit would be practically nil. In all probability it would be more than offset by the saving in gasolene and oil effected with the aid of the engine starter. So far but one manufacturer has taken advantage of the electric starter and lighter as a valuable advertising medium, as well as a real help in increasing vehicle efficiency, and it would seem that there is room for much thought along these lines on the part of the majority of manufacturers.

PUTTING MOTOR TRUCKS TO THE PROPER TRIAL.

While it is a long time since there has been room for genuine doubt as to the economic possibilities of the motor vehicle as a means for the transportation of merchandise, it is quite a rare thing to see motor cars placed in service in such numbers and under such conditions that exact knowledge as to the real extent of their capability is available—knowledge that is not made more or less uncertain by the necessity for allowing for certain conditions that may seem unavoidable.

Such an opportunity is afforded, however, in the case of the delivery service of the Ward Bread Co., whose plans were made and whose plant was laid out with a view to using a hundred motor delivery wagons and not a single horse. The result is just what might be expected. The cars, working under the best possible conditions, have shown that they are equal to giving nearly 99 per cent. of the theoretically possible service; that the cost of current, far from being a serious expense, is a comparatively insignificant item; and that the work of horses is made to appear almost absurd by comparison. In this case not only are the conditions surrounding the working of the vehicles almost ideal, but there is a total absence of what might be termed horse influence, and the system of records is such that all operating expenses are clearly accounted for and nothing is left to be guessed or imagined.

The Ward experience contains an obvious moral for those who hesitate between horses and motor vehicles, and finally decide to put a few motor vehicles in service with the horses and so obtain information as to the suitability of automobiles for the work. While this is all well and good in so far as it relates to the gathering of data on loads carried, road speeds, general handiness and so on, it is decidedly misleading in the matter of costs, for machines that work under conditions as unsuited to their requirements as are horse conditions, cannot be expected to do more than give an approximate idea of their full capabilities. The only trial that is of absolute and precise value is a trial under the special conditions demanded by motor vehicles.

NATIONAL CHAMBER OF COMMERCE

Brought Into Being Under Auspices of President Taft—Its Officers and Scope —Organizations Eligible.

On Monday last, 22d inst., the Chamber of Commerce of the United States came into being under the direct auspices of the President of the United States himself, that being the title adopted for the organization which was brought about as a result of the call issued by Secretary Nagel, of the Department of Commerce and Labor, at the instance of the President. It was largely attended and was marked by unwonted animation.

The plan of organization proved a subject for long and spirited discussion. Some 600 delegates were present, representing various trade organizations, and practically every state in the Union, not to mention Porto Rico, Hawaii and the Philippines. Harry A. Wheeler, of Chicago, served as permanent chairman and had no easy time of it, so vigorous and insistent was the debate which followed the report of the organization committee, which report had been rendered after an all-night session.

Later, Wheeler was elected president of the Chamber, the other officers chosen being as follows: Vice-president for Pacific slope, J. N. Teal, Portland, Ore.; vice-president for South, Asa G. Candler, Atlanta, Ga.; vice-president for East, A. B. Farquhar, York, Pa.; treasurer, John Joy Edson, Washington, D. C., and counsel, J. Francis Burke, Pittsburgh, Pa.

In addition to the officers, the directors are as follows: George H. Whitcher, of New Hampshire; John H. Fahey, of Massachusetts; A. M. Cooper, of Connecticut; John P. Truesdell and Ludwig Nissen, of New York; A. J. Logan, of Pennsylvania; Bernard N. Baker, of Maryland; William D. Mullen, of Delaware; Francis F. Prentiss, of Ohio; Frederick Bode, of Illinois; Harry T. Wicks, of Michigan; August H. Vogel, of Wisconsin; C. G. Craddock, of Virginia; P. J. Kruesi, of Tennessee; Lewis W. Parker, of South Carolina; B. Thompson, of Louisiana; I. H. Kempner, of Texas; H. J. Hodge, of Kansas; Elias Michael, of Missouri; B. F. Kauffman, of Iowa; E. P. Wells, of Minnesota; Everett G. Griggs, of Washington State; A. C. Dickson, of Oregon, and Horace H. Allen, of California.

The general convention then adjourned. Later in the evening the directorate convened at dinner, Secretary Nagel attending for a while, to form its own organization.

The object of the Chamber of Commerce of the United States, as stated in the preamble, is "to affard a clearing house of business opinion and to secure united action upon questions affecting business interests."

Any local, state, interstate, or national organization, having not less than 50 members, organized for business welfare, but not for private gain, is eligible for membership. But national organizations which are combined of smaller organizations must count each one of these as a member, just as a local chamber of commerce or board of trade counts its individual members. In other words, anything like "pyramiding" is voided. Delegate representation in convention shall be on the basis of twenty-five members. The total may not be more than ten delegates, however.

One of the important articles adopted provides that the directors shall submit to the members of the Chamber of Commerce of the United States various questions on which the constituent members shall report back. This referendum is in accord with the suggestion of the President and Secretary Nagle that the new organization be formed so as to advise the government what is the general sense of organized business men of the country as to various questions.

A form of initiative is also provided. Constituent members may put questions up to the directors for reference, if the board approves, to all the members.

The board of directors consists of 25 members. Washington is designated as the permanent headquarters for the chamber, but it is provided that annual and special conventions may be held wherever the directors may designate.

Newark Also Stops Unnecessary Noise.

Following the example of Chicago, St. Louis and other cities, Newark, N. J., has enacted an ordinance, which, if enforced, will stop the horn-tooting nuisance. The Newark law requires that "every automobile shall be equipped with an adequate signal," which is defined as one producing an "abrupt note sufficiently loud to be heard under all conditions of traffic," and provides that it shall be sounded only when it is "necessary as a warning of danger." As the state law forbids the use of muffler cut-outs the residents of New Jersey are in a fair way of obtaining the reasonable peace and quiet which is their due.

Eight Months Lopped from Clark's Term.

George H. Clark, who was suspended for a term of two years for having participated in Barney Oldfields' "outlaw" meets in Los Angeles last year, and under an assummed name, will be in good standing again after the 1st of August. Clark's term would have expired April 1st, 1913, but the generosity which has distinguished the board of late was responsible for the shortening of his term of suspension by eight months.

Famous Car Returns to Actual Service.

By way of emphasizing its desire to assist owners of Thomas cars in maintaining their machines in an efficient condition, the E. R. Thomas Motor Co. has brought its New York to Paris racer out of retirement and started it on a tour of agencies, manned by Neil Nohr and Elmer Miller, two factory experts. Under the auspices of the Thomas service department the once famous machine will tour New York State and then New England, the first stop being Rochester, and its experienced crew will devote its time to helping agents and owners along the lines that are usually included in the term service.

April 27, Philadelphia, Pa.—Quaker City Motor Club's Roadability run from Philadelphia to Atlantic City

April 29-May 4, Burlington, Vt.—Burlington Merchants' Protective Association's annual show in State Armory.

May 4, Santa Monica, Cal.—Santa Monica road race.

May 30, Indianapolis, Ind.—Five hundred miles International Sweepstakes race on the speedway.

May 30, Salem, N. H.—Rockingham Park track races.

June 8, Narberth, Pa.—Track races under the auspices of Quaker City Motor Club.

June 20, Chicago, Ill.—Chicago Motor Club's annual hill climbing contest on Algonquin Hill.

June 20-22, Portland, Me.—Pine Tree Motor Contest Association's reliability run.

June 27-29, Detroit, Mich.—Midsummer meeting of the Society of Automobile Engineers.

July 4-6, Old Orchard, Me.—Beach races under the auspices of the Old Orchard Automobile Association.

August 8-10, Galveston, Tex.—Beach races under the auspices of the Galveston Automobile Club.

August 23-24, Elgin, Ill.—Chicago Motor Club's national stock chassis road races.

September 2, Indianapolis, Ind.—Track races.

October 7-11, Chicago, Ill.—Chicago Motor Club's reliability run.

Minnesotans Form Another Club.

The Montevideo Automobile Club has been launched in the Minnesota city of that name, with these officers: President, J. E. Henry; vice-president, L. O. Norheim; secretary, C. A. Sherdahl; treasurer, G. A. Claggett.

Bolter Heads Michigan Organization.

L. M. Bolter has been elected president of the newly formed Itasca County (Mich.) Automobile Association. The other officers are: Vice-president, William Nesbett; secretary-treasurer, A. W. Sitz.

ALABAMA STARS AT A MIXED MEET

Birmingham Dealers Combine Show and Racing—28 Car Exhibits, Two Slow Races and One Accident.

Sandwiched between several aeroplane and motorcycle events, and in connection with an exhibit of motor cars which were housed in the Exhibition Hall on the grounds, three automobile speed events were run under the auspices of the Birmingham (Ala.) Automobile Dealers' Association, April 18 and 19, on the State Fair track. A little overtime work on the part of Jupiter Pluvius rendered the one-mile dirt track so muddy that the races which originally were scheduled to be run early in the week, were postponed until Thursday, 18th, on which date a 15-mile event and a 10-mile event were run. The honors in each case went to F. Norman, who drove a Buick, his times being 17:16 and 11:25¾, respectively. A 15-mile event, which was run on the 19th, ended disastrously for Cecil Lyons, who jumped the track in his Chalmers car while completing the tenth lap, and created so much excitement that the race was called off. Lyons and his mechanician, Walter Cather, were removed to the hospital.

The exhibit of motor vehicles, conducted by a dozen dealers, embraced 28 different makes of automobiles, one of which, the Great Southern, is a local product. It is a four-cylinder car of more or less conventional design, and was exhibited in four different body styles by the Great Southern Motor Co. The other exhibitors were as follows: Highland Garage, Marmon, Buick, American, Oldsmobile, Regal and Broc electric; Brownell Auto Co., Ford; Birmingham Motor Co., Pierce-Arrow, Chalmers and Rauch & Lang electric; Drennan Co., Overland, Stevens-Duryea and Peerless; Matthews Auto Co., Krit and Firestone-Columbus; Studebaker Corporation, E-M-F and Flanders; Drennen Motor Car Co., Cadillac; Coxe Motor Sales Co., Marion, Apperson and Ohio; Charles Denegre, Packard and Hudson; Birmingham Garage, Thomas and Oakland; Birmingham Auto Co., Lozier and Hupmobile.

For a "National" Non-Stop Contest.

Having tabooed automobile racing as an unsafe sport, the Michigan State Agricultural Society, which conducts the annual fair in Detroit, has practically decided to undertake what aptly may be termed an automobile "merry-go-round." In other words, a national non-stop contest open to all. It is expected that application for A. A. A. sanction will be made during the present week and that the first contest will occur on the roads in and about Detroit during September next, with a view of breaking the record of 12,405 miles, which recently was set by a Warren car in California. The plans of the Michigan promoters are quite ambitious and include the offering of a number of prizes, chief of which will be a challenge trophy of such value that, it is hoped, it will become as famous as the Vanderbilt or Glidden trophies.

Lyon Becomes New York's Secretary.

Frank D. Lyon ,of Binghamton has been elected secretary of the New York State Automobile Association to fill the vacancy caused by the resignation of J. A. Ritchie, of Syracuse. Previously Lyon was deputy supervisor of the New York State Road Commission and a prominent figure in Republican political circles. He is considered one of the greatest experts on road construction in this country. The Empire State Motorist, the official organ of the State association, which was founded by J. A. Ritchie, has been sold to an association that will be incorporated and will be published by a separate company. A. J. Deere, president of the N. Y. S. A. A., is one of the principal backers of the enterprise.

Warren's Non-Stop Record Recognized.

The official acceptance by the Contest Board of the American Automobile Association of the non-stop engine record of 12,404.9 miles by a Warren-Detroit in Oakland lot, Februaray 4th to March 9th, was promulgated this week. The official report states that 748 gallons of gasolene, 48.25 gallons of lubricating oil and 41 gallons of water were used during the interval. It is also announced the records made on the 14th inst. by Louis Disbrow at San Jose for 15, 20 and 25-mile distances from a standing start have been officially accepted.

Denver To New York Tour Revived.

The Denver to New York automobile touring contest, which was undertaken and abandoned last year by the Denver Chamber of Commerce, has been revived, and it now is given out that it probably will be started on June 1st next. The Chamber of Commerce has interested a number of the more prominent dealers and several meetings have occurred at which, it is stated, at least ten entries have been pledged, with twenty others in prospect.

No Strings on New York's Reciprocity.

Despite reports to the contrary, which apparently had their origin in New Jersey, the state of New York will not interpose any barrier in the way of reciprocity between the two States. The Attorney-General of New York has handed down an opinion that New Jerseymen, whether owners or chauffeurs, will be free to enjoy the roads of New York for a period of 15 days in each year—the period fixed by New Jersey's law.

Chicago Truck Contest Declared "Off."

The Chicago Motor Club has abandoned the four-day truck contest which had been programmed to occur May 15 to 18 next. It may be held later in the year.

CONTEST RULES AGAIN REVISED

Numerous Changes of Far-Reaching Nature—New Definition of "Contest" and Provisions to Promote Safety.

After undergoing the refining test, as applied by the A. A. A. contest board and the Manufacturers' Contest Association, the A. A. A. contest rules, as formally promulgated this week by Chairman Schimpf of the A. A. A., disclosed not a few changes of far-reaching import.

The definition of "Contest" has been so modified as clearly to indicate what motor car events will be sanctioned by the A. A. A. and now reads as follows:

Contest—Any competition of two or more motor cars, governed by rules, in which entry fees may or may not be charged, or prizes may or may not be offered, or in which speed or durability are determining factors in evolving a winner.

The definition of "Automobile, Motor Car or Car" has been changed so as to include three-wheeled vehicles.

The minimum weights heretofore prescribed in stock chassis events have been eliminated and stock chassis contests will be governed by piston displacement, as are Class "C" events.

No car or chassis competing in events held under price or piston displacement classifications is eligible for any division except that to which its price or piston displacement entitles it.

Sanction fees remain unchanged, except that a fee of $1,000 is provided for events of 100 miles or more held on specially constructed speedways, such as the Indianapolis Motor Speedway, the Los Angeles Motordrome, etc.

To rule 17 which reads:

Reserved Territory—No sanction shall be granted to any promoters to hold a contest in the territory of an affiliated club, until the Contest Board has conferred with such club has been added:

Any objections which an affiliated club may file against the promotion of any contest in its territory must be supported by bona fide reasons for such objections."

The following new rule has been incorporated:

17A. No sanction shall be granted to any club, association or individual for any contest other than one to be promoted and conducted by it. Any misrepresentation or transfer of sanction to a second party for a consideration shall invalidate the sanction and render the club, association or individual liable to disqualification and ineligible for further sanctions.

Under new rule 33A, mechanicians must be carried in all road races, and in all events of 50 miles or more held on beach, speedway or track.

No driver or mechanician under 21 years of age will be permitted to participate in

Digitized by Google

sanctioned events, and no person under 21 years will be appointed an official.

Registry cards will no longer be issued to drivers in reliability contests, but such drivers will be required to register with the referee of each reliability run prior to the start, on a form specially prepared. No regisgtration fee will be required and such registration applies only to that particular event.

To rule 110 on the "Change of Crew" of a car is added the following:

"Should the mechanician leave his seat for any reason whatsoever at any time during the race, the driver must not continue until the mechanician is again seated in the car. In case of disability or accident to the mechanician which may necessitate leaving the car, the driver may, after stopping and investigating, proceed alone to pits and make application to the referee for instructions."

The powers of the official referee of a contest have been somewhat enlarged by these two rules:

"He shall have the right to terminate a race before its scheduled finish, if emergency demands such action, and in such case no award shall be made."

"He shall have the right to temporarily stop or delay a race in case of impending disaster. Upon signal to stop, the cars must line up in front of their pits (or in the paddock) and during the time the race is discontinued they shall be in charge of members of the technical committee and no work of any kind shall be done upon them."

The deposit prescribed to accompany written protests filed with the referee, heretofore ten dollars in all cases except reliability tours, has been raised to twenty-five dollars for all events. It is hoped that a required deposit of this amount will result in a decrease in the number of frivolous protests.

The use of flags to signal contestants in track and road races has been made consistent. Heretofore the red flag in track races indicated "Stop" and in road races "Course is clear." The various flags and their use is shown:

Red flag—Course is clear.

Yellow flag—Blocked course; stop.

Green flag—You are entering your last lap.

White flag—Stop at pit on next lap for consultation.

Black and white checkered flag—You are finished.

Black flag with white center—A competitor is trying to overtake you. (Road judge's flag for use on narrow stretches of course.)

In stock car and stock chassis events the use of detachable or demountable wheels which do not involve the change of wheel bearings or that portion of the hub carrying the bearings is not permitted except such wheels are regularly supplied as stock equipment. In non-stock events such demountable wheels are permitted on same basis as the use of detachable or demountable rim equipment.

Considerable time and thought have been devoted to the matter of taking proper measures for the protection of spectators and competitors the following rules having been made for that purpose:

Rule 203. Fences—Fences should be of such a nature as not to endanger the lives of drivers and mechanicians of competing cars. The pole or top rail of fences at the inner and outer edges of the track on the curves must be removed, starting at a point where the curve begins and continuing to a point 25 feet beyond where the curve ends, measured in the direction in which races are run, i. e., with the left hand of the driver toward the inner fence.

Neutral Zones—Neutral zones must be established and maintained during the running of races. These zones should be 40 feet in width on the inner and outer curves opposite where the pole or top rail of the fences is removed, as required by the foregoing rule, and 30 feet in width on the straightaways.

Rule 204. Ditches, Holes or Obstacles—Ditches, holes or obstacles must not be permitted on the track between the inner and outer fences.

Rule 205. Anti-Dust—Adequate measures must be taken for the prevention of dust on the track. The use of water is not permitted, and dust must be laid by oils, calcium chloride or other similar preparations approved by the Contest Board.

Rule 206. Official sanction for track events is issued conditional upon a strict compliance with the above rules, and sanction shall be revoked in case of failure to meet each and every one of these requirements.

Handicap events will hereafter be timed from the start of the "limit" man or first competitor away from the line.

The number of starters in a track race shall be limited to one car for every 400 feet of track. This will permit 13 starters in a race held on a one-mile track and seven in a race held on a half-mile track. Starting positions shall be assigned in the order in which competing cars are presented to the starter, unless otherwise specifically arranged, and there shall be 4 feet between the hubs of contesting cars.

Touring events in which other than registered stock cars may be entered can be run under Class "E" of the general classifications and under the conditions of Grades III and IV. In case of tied scores, winners shall be decided by lot.

Reliability contests of Grades I and II shall be open only to registered stock cars, whereas contests of Grades III and IV may be (1) restricted to registered stock cars or (2) open to any car privately owned or otherwise, regardless of registration.

The revised rules in book form are now in the hands of the printer and will be ready for general circulation within the next week or two.

The revised rules for commercial vehicle demonstrations also are in hand and shortly will be made public.

Who Is a Chauffeur in Minnesota?

"What is a chauffeur?" is a question which has bothered owners of automobiles—and also attorneys—in many States, and which just has been answered by the legal representative of the State of Minnesota. He has ruled that a chauffeur is any person who drives a car on public streets as the employe of another, whether his employment be occasional or incidental. The ruling resulted from complaints to the State examining board of arrests of persons driving cars without licenses who were not professional chauffeurs. Another ruling is that fire and police cars and drivers need not be registered.

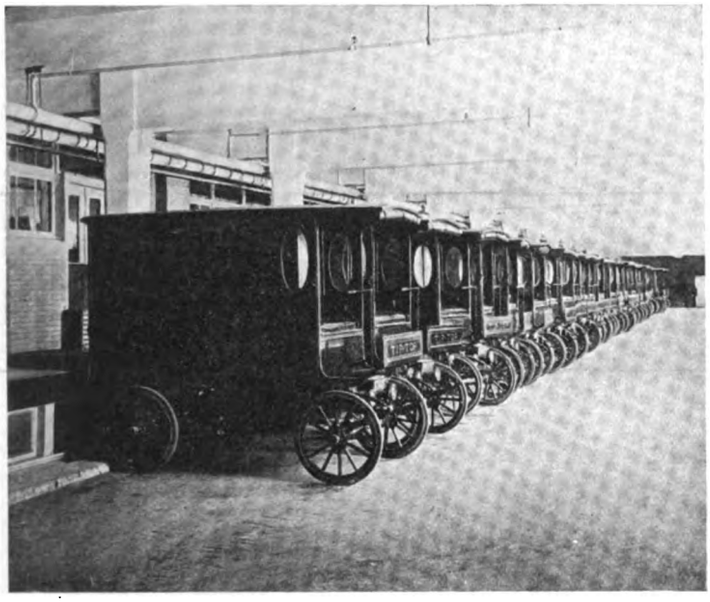
ELECTRICS IN BREAD BUSINESS

Their Advantages Over Horses Proven by Facts and Figures—Ward's Address to Electric Vehicle Association.

It is quite a common occurrence for a concern contemplating the extensive use of electric commercial vehicles to make a preliminary test with a few machines, and, basing their cost estimates on the information gained through their use, decide that the cost of current for charging the batteries is likely to be exceedingly high. That such is by no means the case is conclusively shown in a paper read by Charles A. Ward before the Electric Vehicle Association of America at its monthly meeting on Wednesday last, April 23d. In this paper, which is entitled "The Electric Vehicle Installation of the Ward Bread Co.," it is shown that the cost of electricity for charging the batteries of the 100 machines comprising the fleet is the smallest single item of expense connected with their operation, and that the cost of current could be doubled without becoming a particularly serious matter. Furthermore, the figures quoted in the paper, which are taken from the working records of the machines, indicate that the service efficiency of the cars —that is, the service actually given in proportion to the possible service—was 98.83 per cent.

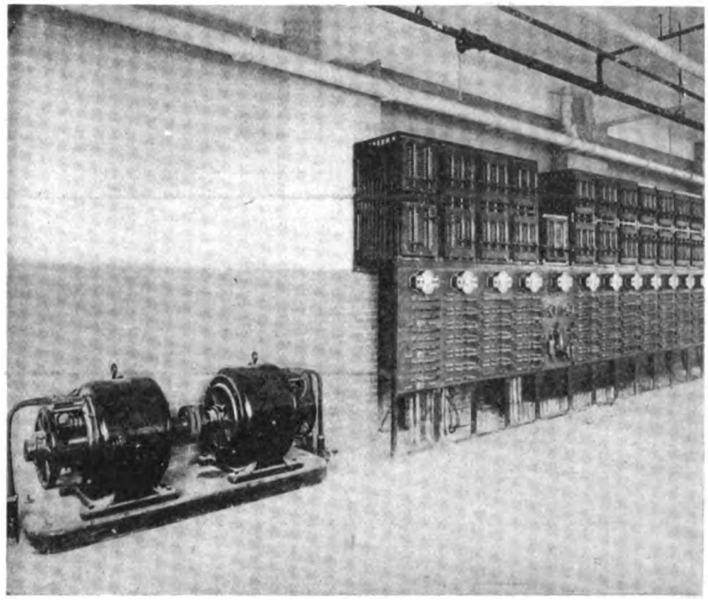
The Ward Bread Company operates two plants in Greater New York, one in Brooklyn and the other in the Bronx, but the paper dealt only with the Bronx plant. After referring to the early experiments of the Ward company in its efforts to obtain data for use in building up a delivery service on a large scale, Ward briefly describes the cars used, which are enclosed battery wagons of half a ton capacity each, with sliding doors back of the driver's seat to give access to the interior, and with single motor drive, built by the Ward Motor Vehicle Co., and then describes the garage. In reality this is the shipping department—a somewhat startling combination, and one that is made possible only by the extreme cleanliness of electric motor vehicles. The central part of the ground floor of the plant is a glass enclosed square surrounded by loading platforms, outside of which is the open space in which the vehicles stand. The bread is delivered to the central enclosure and thence transferred to the wagons, which back up to the platforms for the purpose of loading.

When placed for loading the vehicles are packed side by side so closely that they stand almost hub to hub, concentrating to a minimum the area which must be covered in loading. Separated from the main room of the garage are the battery, repair and charging rooms, so that there is no possibility of gases or odors coming in contact with the bread. For charging, direct current at 110 volts is used; this voltage is sufficient for the lead batteries used in 85 of the cars, but for the 15 which are equipped with 72-cell Edison batteries additional voltage is obtained by the use of a 35-volt booster set. All vehicles are charged while standing backed up to the loading platform; each machine is numbered and it has its own place at the platform, and from under the platform there extends a charging cable and plug, for each car, correspondingly numbered. The switches on the charging board are numbered also, so that the making of current consumption records is much simplified.



A complete, and yet simple, system of records is maintained, and is described as follows:

"Three sets of records are kept, namely, a daily vehicle report card, a five-weeks' report card and a parts renewal card.



"The vehicle report card is used daily by each vehicle operator. A clean record card, to be found in a pocket in the front of the vehicle, is a notification to the operator that his car has been properly inspected, repaired, washed and charged, and as such is ready for his use. Should no card be found he is to make immediate inquiry of the garage superintendent for correct information. Should his car have to remain in the garage, a substitute is given him for his use that day or until his regular car has been repaired.

"The record above referred to is kept by the operator until he is through for the day. It then bears his name, vehicle number and information as to the number of trips made, total mileage and operator's report as to the condition of the vehicle when turned in. Accidents must also be reported on this card. Completed, the card is then turned over to the garage superintendent, who despatches inspectors and repair men, who make any slight repairs necessary, oil the vehicle and turn it over to the washing department. This completed, the vehicle is turned over to the charging department, where it is then charged and made ready for duty the following morning. Records are made on this card of all repair parts and the time required to install the same. Records are also made of volts, amperes, hours and time required to charge the battery.

"It can then be seen that the totalized costs on the record card represent all operating costs for the day. I should have added that these cards also bear an additional expense item representing the total sum of all other garage expenses, including superintendent's time, labor of all kind, acid, water, tools, sponges, chamois, soap, oil, grease and all other items incidental

VEHICLES AT LOADING PLATFORM

SWITCHBOARD AND GENERATOR

Digitized by Google

to the proper care of the vehicles in question. Every expense is put upon these cards except the items of depreciation and interest on investment. The costs shown later, then, will include for the period given every other expense save the two last-named items.

"From the vehicle report card we pass to the 'Five Weeks' Report' card. Each of these reports covers information for a period of five weeks on one vehicle. Such information as the following is entered: Date, condition of vehicle, battery number, miles per day, power cost, accident cost, repair cost, total cost, route number and any additional remarks. For the sake of simplicity, all costs except the cost of current are included under the heading of repair cost.

"The last record card is a renewal of parts sheet which embodies the vehicle specifications, factory number, date put in service and the dates on which tires, bearings, batteries and other wearing parts were replaced. This gives a line on the length of life of the various parts and acts as a check on not only operator and garage, but the makers of parts and factory as well.

"No attempt has been made to go further into detail than outlined above, as the information collected is believed to cover practically every item to be desired.

"In coming to the costs proper, I would like to say that no preference was given looking toward the selection of what might be termed a good period. As might be surmised from the five-week report cards previously referred to, the Ward Bread Company close their books every five weeks. Hence the costs following cover the entire operating expense, except interest and depreciation, on the entire fleet of one hundred vehicles. The last period available for use in this paper began January 29, 1912, and closed on March 2, 1912, and so far as weather conditions are concerned was surely not a favorable one.

"The five weeks' cost report on vehicle No. 328 shows that this vehicle ran thirty working days (five weeks), an average of twenty-five miles daily, at a total cost, except interest and depreciation, of $19.57. This vehicle had the banner record for this five weeks' period; had no acident cost and practically no repairs.

"So that you may see the worst side as well, I will show the record covering the worst vehicle of the group. This was vehicle No. 163. It ran thirty days (five weeks), doing twenty-eight miles daily at a total cost of $64.21. A new tire, its battery washed and some repairs account for the high cost.

"As it is impossible to show each of the one hundred record cards for this period, I shall have to ask you to accept a summary of all the figures.

"These records show that during the period a total of sixty-six thousand and twenty-three miles were traveled, or an average mileage per car of twenty-two miles per day.

"The total power cost was $597.63, or $.199 per day per car; an average cost per mile of $.009.

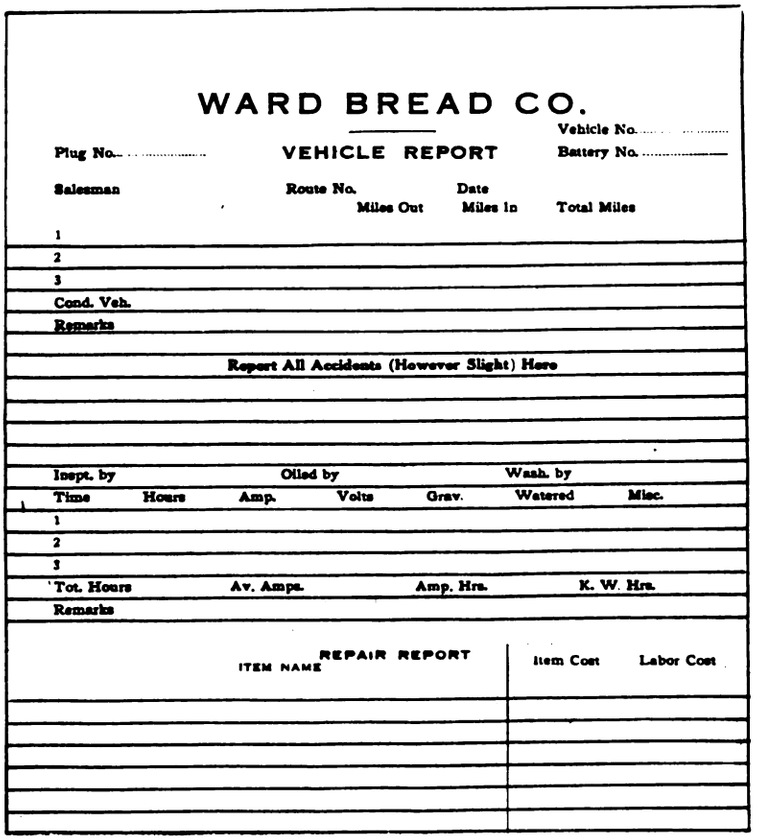
"The total accident expense was $84.65, or $.0182 per car per day. Per mile this figures $.00083.

"The total repair cost, which cost, as previously stated, covers all items of expense in connection with the garage and the maintenance of the vehicles, was $2,400.50, or an average of $.80 per day per car. Per mile this figures $.0363.

"To summarize the above we have the total of these figures, or $3,082.78 as the entire cost for thirty days (five weeks) of operating the entire fleet of one hundred electric vehicles exclusive of interest and depreciation.

"Per day the cost was $102.73, or per vehicle per day, $1.027. Per mile the figure is $.0466.

"One thing should also be noted, namely, the small comparative cost of the current to run these cars. In other words, this item, commonly so much discussed and complained about, is the smallest item of expense. Indeed, it could be doubled and only affect the total operating cost by 20 per cent.; surely nothing to be greatly alarmed over.



"Before closing I should like to say that during the period above referred to twenty batteries were washed, a number of sprockets and chains were renewed, as were also a number of tires.

"An inspection of the records shows that, during the period, the shortest route was twelve miles and the longest forty-one miles. During the summer and fall the longest route was made by what was called a three-tripper and which ran on one charge sixty-three miles. This was not a regular route.

"The longest regular route was one to Port Chester and was a little over fifty miles daily. This vehicle ran until some time in December, when a gas car was put on for the winter service.

"Another interesting fact obtained from the records cited was what might be called the efficiency of the service. This was determined by dividing the total number of car days operated by the maximum possible car days (100 X 30 or 3,000). This efficiency proved to be 98.83 per cent; certainly little to be desired in the way of reliability of service; especially when one considers the fact that the results are for a winter period. The system above referred to is being changed from time to time, as experience shows to be advisable. Experiments are being made almost continually looking toward the controlling of operating conditions that will better even the foregoing records.

"That the end is not yet, it is safe to assume; an example of this is clearly shown by the low costs due to accidents. This figure, you will recall, was but $84.65 for the entire fleet over the entire five weeks' period. Let us hope that other means may be found whereby the remaining costs will be lowered as well. When this has been attained, the millennium of the electric vehicle will have arrived."

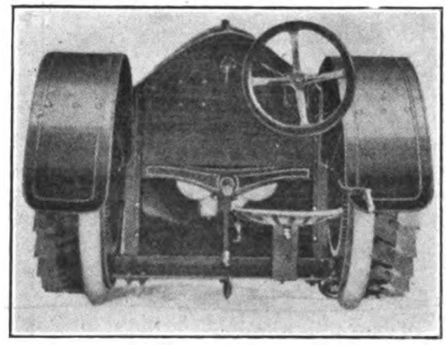
LAMBERT BRINGS OUT TRACTOR

Machine That May Be Used on Roads and Fields—Three Wheels and Friction Drive Its Features.



If there is one type of machine which more than any other requires many changes of speed or "gear" ratio, it is the farm tractor, which necessarily must move slowly and with great power when dragging plows, but is not held down to such low speeds by extraneous conditions when on the hard road. This doubtless was one of the considerations that influenced the Buckeye Mfg. Co., of Anderson, Ind., in applying the friction drive principle embodied in the Lambert car to the Lambert agricultural tractor—in England they probably would call it an "agrimotor"—designated an orchard tractor, which is shown in the accompanying illustrations.

While the first requisite, high tractive capacity, is obtained by the use of a 40-horsepower motor driving through friction disks, there are other requisites which are of almost equal importance. A machine for use in orchards must be extremely low, and the Lambert tractor, through underhanging and general compactness and by the low placing of the driver's seat in the extreme rear, has been kept down to a height of 42 inches. It must be capable of making very short turns, and this is permitted by the use of a single steering wheel in the front and the shortness of the wheelbase. And when on hard roads the rear wheel cleats, which are essential to traction in soft ground, are kept out of contact with the road surface by solid rubber tires which form the tread for road work, permitting fair speed without damage to the road surface. A maximum speed of ten miles an hour can be attained.

The motor and change-speed mechanism, essentially the same as used in the Lambert car, and including a 40-horsepower four-cylinder motor and the Lambert gear with one driving and one driven disc, are placed in the tractor in a position which is the reverse of that of the motor and drive in the pleasure cars—that is, the motor is in the rear and drives forward to the discs, which in turn drive backward to the tractor wheels. This brings the weight of the motor almost directly over the rear wheels, where the weight is needed. All the mechanism is covered by two hoods, one over the engine and the other over the change speed mechanism, the front being formed, as usual, by the radiator. The driver occupies an iron seat of the skeleton type common to agricultural machines, and steers with a regular automobile hand wheel. The single steering wheel in front is mounted on a very large hub which, as the illustration shows, is essentially two rings, the outer one carrying the inner ends of the spokes and forming part of the wheel and the inner ring remaining stationary, so far as rotation is concerned. Within the inner ring is the pivot upon which the wheel turns in steering, the pivot crossing the ring diametrically and vertically. Between the inner and outer rings there are presumably antifriction bearings, with either balls or rollers. The rim of the front wheel is a broad steel band with the rubber tire in the middle; enough of the band projects on each side of the tire to form a support when the tire sinks in soft ground. Very heavy steel wire is used for the spokes.

LAMBERT THREE-WHEEL ORCHARD TRACTOR WHICH EMPLOYS FRICTION TRANSMISSION

LAMBERT TRACTOR, REAR VIEW

No little ingenuity is displayed in the construction of the rear wheels, which, of course, are depended upon to carry practically all the weight and at the same time transmit power. The tread may be said to be triple. One the inside, next to the frame, is a solid rubber tire which is of somewhat greater diameter than the rest of the wheel, so that it carries the weight when the ground is hard. Next to this is a flat steel band similar to that on the front wheel, but with projecting cleats, or, properly speaking, plates, which dig into soft ground and resist the tendency of the wheel to slip. Outside of this there is a ring of plates which are continuations of the plates on the steel rim and, of course, work in the same way, giving any additional traction when needed. The cleats, or plates, clear themselves of soft earth automatically. Strong steel spokes are employed on the outside, while the inner side consists of a broad steel ring with very short spokes at the center. All three wheels are covered by very wide mudguards.

The usefulness of the Lambert tractor does not end with its ability to drag plows

Digitized by Google

or wagons, for it is designed also to drive farm machinery, one of the disk shafts projecting through the frame near the front of the hood and taking a belt pulley which forms part of the equipment of the machine. The shaft can be seen quite plainly in the illustration. This arrangement increases the field of usefulness of the machine very considerably, as it can be kept in service driving saws, feed-cutters, threshing machines and the like.

Keeping Open the Breather Tube.

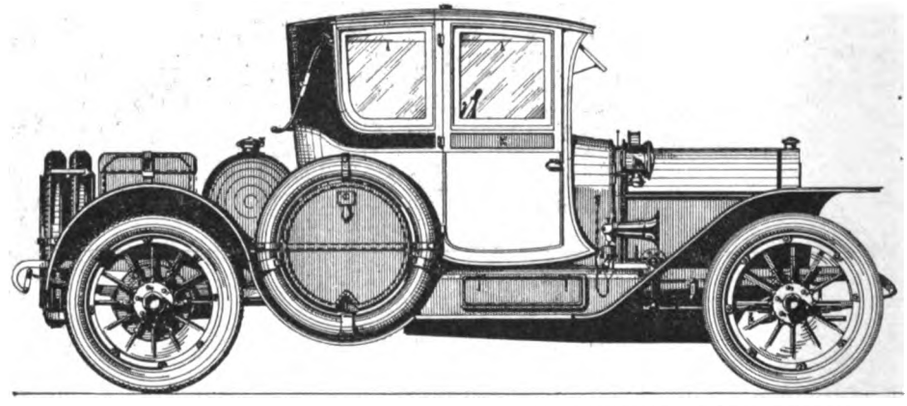
The importance of keeping the opening of the breather tube, free and clear from obstruction cannot be emphasized too greatly, especially with two and six-cylinder motors. With the four-cylinder motor, if the crank case is hermetically sealed, there is practically no compression in the case, because while two pistons are traveling upward the other two are on the downward path and the compression of the air by the latter is exactly balanced by the rare faction by the former. With a two-cylinder motor, however, both pistons are traveling either up or down at the same instant and the compressed air is liable to blow the lubricant out of the main bearings and the bearings of the cam shaft and a hot bearing will result. The same is true with a six-cylinder motor, wherein the cranks are set at angles of 120 degrees.

Wiring That May Increase Efficiency.

Occasionally it happens that the speed and efficiency of an electric vehicle, either commercial or pleasure, can be slightly increased by removing the wiring and replacing it with wire of a larger size. This is more apt to be true of old machines than of those of recent origin, which usually are well wired. The way to find out if an improvement can be made is to go over the wiring immediately after the machine has been doing hard work for a considerable time. If the wire is too light it will be more or less heated. If no heat is noticed it is safe to assume that the wiring is of ample capacity.

Tires That Require Equal Air Pressure.

The equipment of either pleasure cars or trucks with dual pneumatic tires necessitates that even greater care than is usual be taken to see that the proper pressure of air is maintained in them. If duel tires replace single tires the pressure may be mainted slightly lower, for each tire will be subjected to less strain. In any case, however, great care should be taken to insure that the pressure in both tires of a dual set is maintained exactly the same. If it is not, one tire will support more than its share of the load and rapid depreciation may be expected.



Closing Oil Holes Before Painting.

Before having the car painted cotton should be stuffed in all of the oil holes, which serve to conduct lubricant to the spring shackles, etc.

COLUMBIA ADDS COUPE-LANDAULET

It is Mounted on Knight-Engined Chassis and Has Unusual Equipment—Running Water a Feature.

In adopting as a stock body style the combination coupe-landaulet which for some time past has been much in vogue abroad, though up to quite recently it was more or less of a curiosity on American shores, the United States Motor Co. has not been content to accept existing designs in their entirety, but with characteristic progressiveness has developed a type of body of this class that is different in many ways and which is eminently suited for long-distance touring. In the main, the new body is a coupe-landaulet, though in modifying existing designs the manufacturers have incorporated a number of features that bid fair to make the body more than ordinarily popular. In fact, two of the cars already have been sold to San Francisco physicians, orders for immediate delivery having been telegraphed to New York.

COLUMBIA-KNIGHT COUPE-LANDAULET—AN UNUSUAL BODY DESIGN

Though the new car is a distinct novelty and is somewhat fantastic as regards the body design and equipment, it is practical withal, and is calculated to permit the driver to tour extensively in defiance of the elements. For fair weather it is a simple operation to let down the back, and for foul weather the occupants may be, as Franklin said, "as snug as a bug in a rug" with the back raised. The joints between the rigid portion of the body and the back are cunningly hidden and are so constructed that it is a physical impossibility for either water or dust to enter. Provision for seating two passengers side by side is made, and a third may be accommodated in emergencies on a swinging seat facing the driver's companion.

As regards the equipment, it is more complete than is usual, as becomes a car that is to be used all the time over all kinds of roads and under all kinds of conditions. The gasolene capacity, for instance, is 60 gallons, and no less than six spare tires are carried, two of them being in racks behind the gasolene tank and trunk and two in cases on each running board. Spare tubes and tools are carried in a compartment in the trunk and additional storage space is provided in the spare tire cases. One of the unique features of the car is that there is a fresh water tank built into the roof and pipes leading to a faucet inside the body. The water is to be used for ablutions or for drinking or for replenishing the radiator on long runs.

The body is mounted on a stock model Columbia-Knight chassis of 129 inches wheelbase, and in addition to the features that have been mentioned is equipped with the accessories as listed for the other Columbia-Knight cars that are catalogued. The bore and stroke of the motor are 4⅞ inches and 5⅛ inches, respectively, and the rated horsepower is 38. Other excellent features of the chassis are the large cone clutch, the selectively operated four-speed change gear mechanism, with direct drive on fourth speed, and the full-floating rear axles.

"Trick" in Towing Electric Vehicles.

One of the things that occasionally will occur where electric motor vehicles are used is the exhaustion of batteries while on the road. In such a case it often is necessary for another battery machine to go one and tow the "dead" machine home. And it sometimes will happen that the only machine available for the rescue will be one so small that there may be doubt of its ability to get through the job without burning out a motor. If the work must be done by the little car, the best way usually is to disconnect the battery leads from its motor and by means of long wires connect them to the motor leads of the big machine, cutting out the "dead" battery first. Then the big car can be run on the battery of the little one, which is towed. The brunt of the work is borne by the battery, but if the pull is not a long one it is not likely that the overload will do any permanent harm. This measure is, of course, only for emergency use, but has been made use of with good results in several instances.

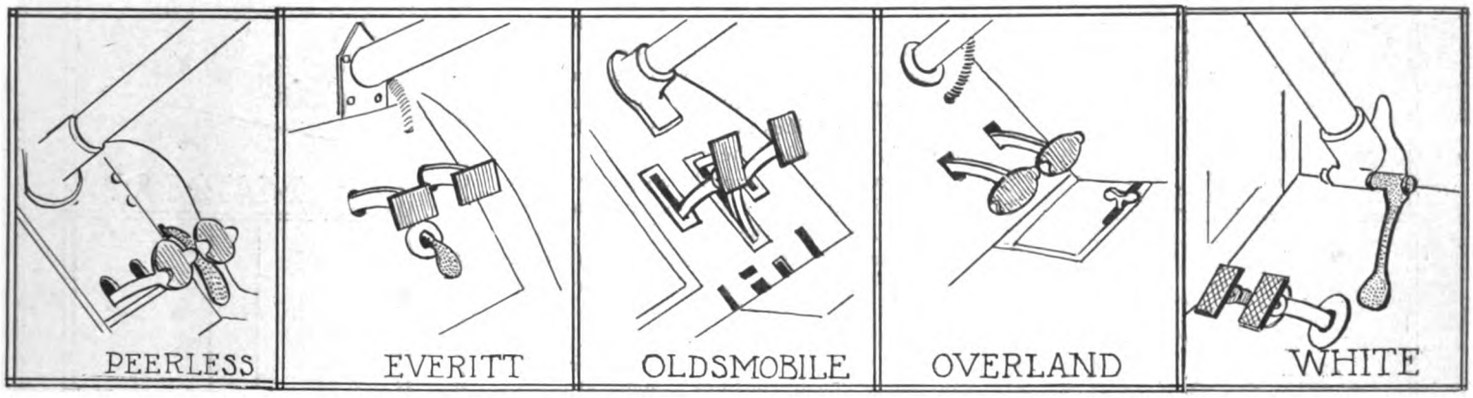
IS THE ACCELERATOR TOO MUCH OF A GOOD THING?

The Pedal-Operated Throttle Lever as a Promoter of Accidents and the Steps Which Might be Taken to Render it a Safer Convenience—Accessibility That Encourages its Continual Use and Frequent Abuse—Results That may be Expected to Follow.

One day last week a young man of wealth and social prominence was sentenced for manslaughter to an indeterminate sentence of from five to ten years imprisonment in a New Jersey penitentiary. He was charged with reckless driving and his crime consisted of running over and killing a pedestrian and then running away. His chief defense was that in the excitement of the moment in attempting to avoid the pedestrian his foot accidentally came in contact with the accelerator instead of the brake pedal, and though the circumstances surrounding this particular instance would seem to warrant the jury's verdict, it is but one case of many wherein the accelerator has been forced to shoulder the blame and it serves to indicate more forcibly than ever that after all there may be more in the excuse than at first appears on the surface.

This case and others like it suggest that perhaps the accelerator is made too accessible—that it might be better to make it harder to get at, for as originally intended it was merely an auxiliary and not the main throttle controller, in which capacity it still serves its best purpose. As for the origin of the device, it is not difficult to trace either its inception or its steady rise to popularity.

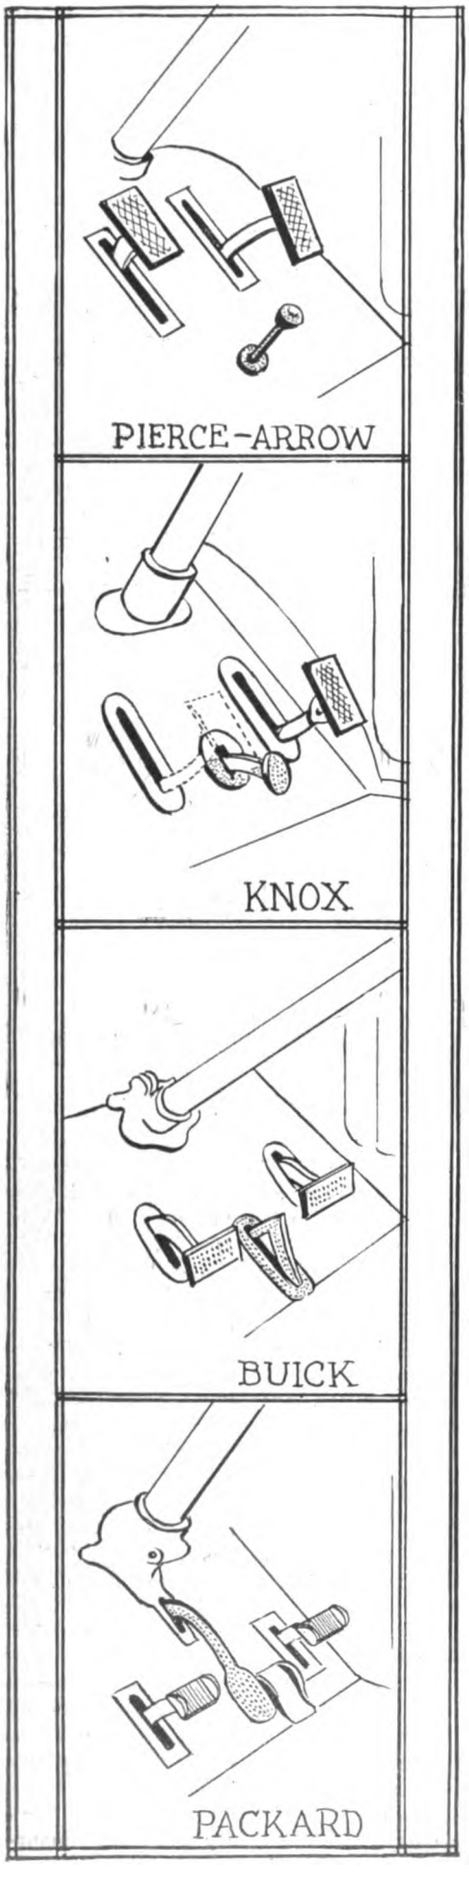
Years ago, when the automobile industry might be said to have donned its swaddling clothes, let alone doffed them, certain daring spirits, following the instinct which is strong in most human breasts to excel—to go further and faster than anyone else—embarked in the hazardous business of automobile racing. And then, as now, the handling of fast-moving vehicles which depend for their direction of motion upon the continuous exertions of their drivers, was not, and is not, child's play. It was, and still is, a strong man's job. Which means that both hands must be on the steering wheel at all times. Consequently as both hands were employed in the very necessary occupation of steering the vehicle some other means of operating the mechanism that controlled the speed of the car had perforce to be evolved.



The answer is to be found in the pedal-operated throttle, or the accelerator, as it generally is styled. From an insignificant beginning on one or two racing cars, the popularity of the accelerator steadily has increased until at present the number of manufacturers who do not equip their products with the device almost might be counted on the fingers of one hand, or on two hands at least. When the accelerator first put in an appearance it was viewed skeptically, but today the car that is without an accelerator is the exception and not the rule.

When the automobile industry commenced to don the habiliments of full-fledged growth, to enlarge the metaphor, accessibility became a fetish, which is as it should be. It is comparatively easy to trace engineering progress in the efforts or manufacturers to render their products simpler and more easily handled. Clutch and brake pedals, however, have remained substantially in their original positions and otherwise have altered but little. But from an accessory, an auxiliary to the operation of the car, the accelerator gradually has assumed to a position of very much greater responsibility; from being tucked away, out of the way, where its use was discouraged, it has come to be placed right out in the open. Its continual use is encouraged by placing it in the most convenient and most accessible position, where the driver's foot most naturally rests.

Of course every attempt to increase accessibility or to simplify the operation of a vehicle is laudable—provided the ends attained are positive and not negative, no matter how they are viewed. But it is an open question whether making the accelerator as accessible as it has been made can be viewed in the light of a positive advance, or, to put it in even simpler language, as a real advantage. It has been demonstrated not once, but many times, that its present accessible position may lay the driver open to accident that would not have been so likely, at least, if the accelerator had been absent, or if it had been less accessible and consequently less likely to be depressed accidentally.

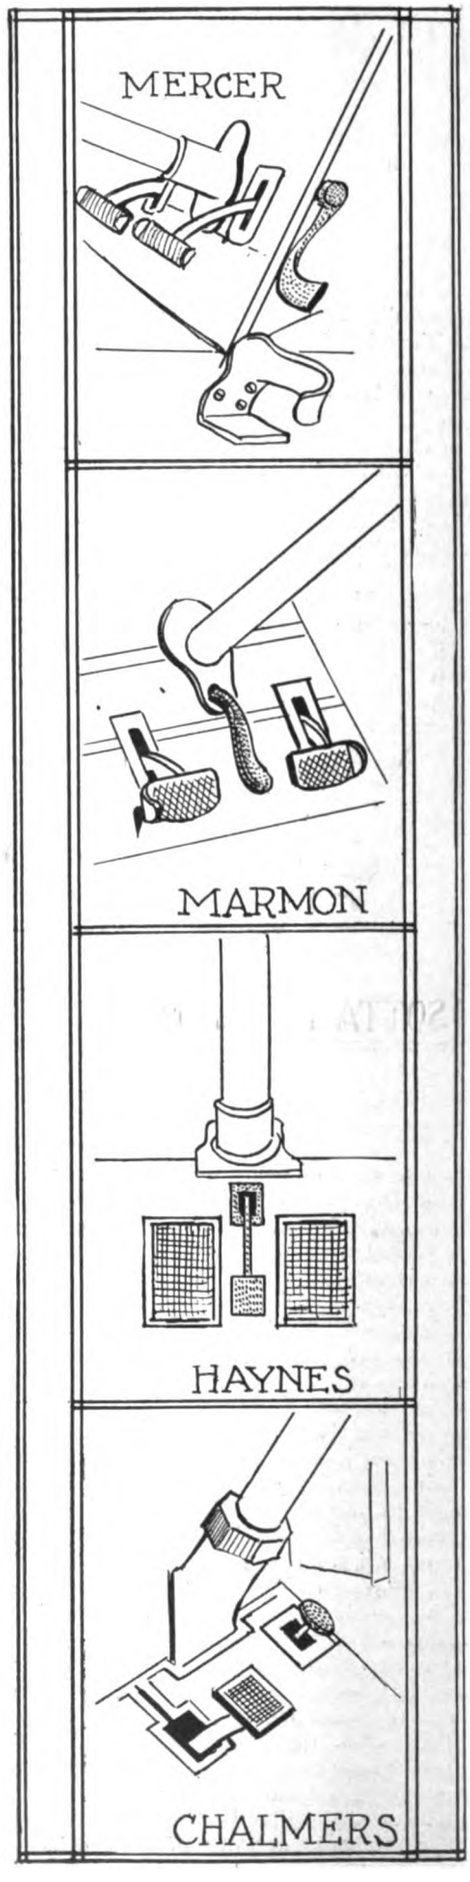


There are many reasons why the accelerator should be less accessible, so that its continual and general use may be discouraged. It is probable that a canvass of the better known manufacturers as to the status of the accelerator would reveal the fact that it does not occupy a very prominent place in the affections of automobile engineers, for there are few devices which may be so easily used in a manner that works damage on the motor and the rest of the car as well. As just one indication that this is so the case of one of the biggest manufacturers might be cited. Up to a little over a year ago this manufacturer would not equip his products with an accelerator for this very reason: It conduced to engine abuse. Popular demand made the fitting of an accelerator necessary, but that does not say that the manufacturer approves of the device.

To go to the other extreme, it is perfectly true that there is any number of manu-

WHERE ACCELERATORS ARE POSITIONED ON FIVE PROMINENT AMERICAN CARS

Digitized by Google

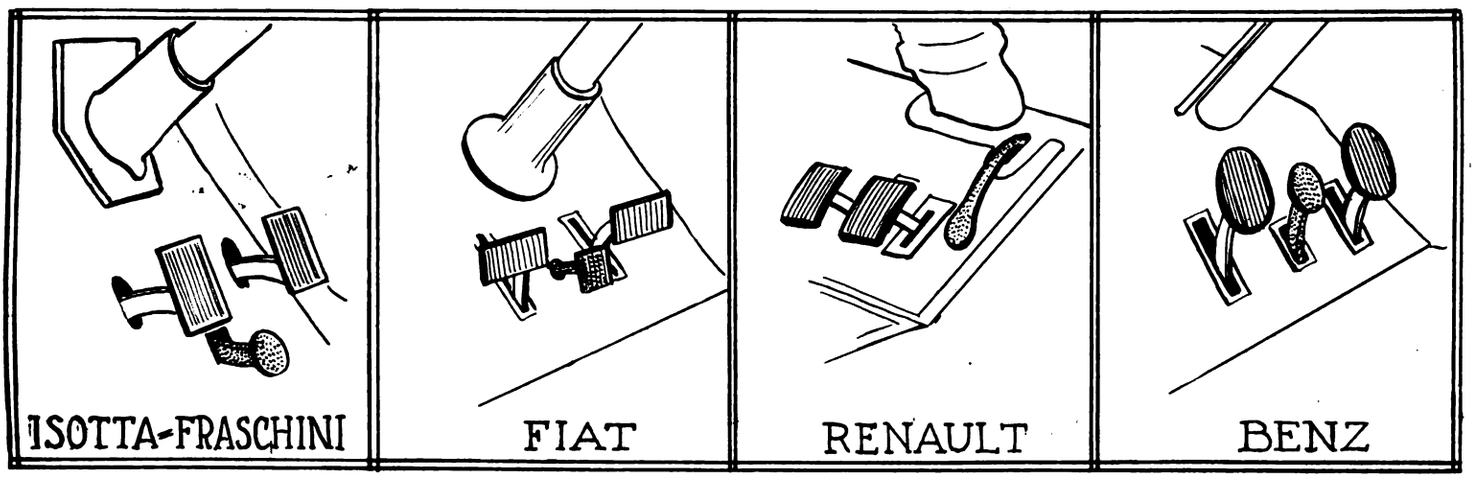


facturers who do not equip their products with hand-operated throttles, but rely entirely upon an accelerator; for instance, the fleet of taxicabs that ply for hire in New York City. But that is no criterion, for, as everyone knows, taxicab drivers are noted for their collision-proclivities, and who is to say whether the position of the accelerator, which must be accessible when it is used at all times, is not responsible for some of the accidents at least?

In any discussion of the relative merits and demerits of the accelerator as a desirable adjunct it becomes apparent that it has one undeniable advantage, to wit: When it is necessary to apply the brake, the operator's foot must be lifted off the accelerator, which automatically closes the throttle and chokes down the engine speed. Of course, leaving mechanical considerations aside, it makes little difference whether the engine speed is reduced or not as long as the clutch is disengaged. But if the operator should neglect to disengage the clutch the car would be stopped more quickly if the engine speed was low than it would if the engine were running faster.

Apart from its influence on the accident column, if the accelerator could be dispensed with or something done to lessen its use, it probably would be found running costs would take a tumble and the wear and tear on engines and cars would be considerably reduced. The reason is thus: No road is absolutely smooth, and every time the car jounces over an obstruction there is a tendency for the foot of the operator to descend slightly and open the throttle a little. If the spring which returns the pedal is light then the spasmodic running of the engine under the alterations of the throttle opening may be very noticeable. Obviously such jerking, such alternate opening and closing of the throttle, when to all intents and purposes it should be maintained set at a certain mean opening, causes excessive gasolene consumption and increased wear and tear on the engine and the car. When the throttle is open for a moment and then closed again an increased amount of mixture is drawn into the cylinders and is burned. But the weight of the car is such that the momentarily increased power is not sufficient to increase the car speed. Consequently, the gasolene is wasted and an extra strain is put on the engine. Incidentally the strain is out of all proportion to that which is sustained when the car speed is accelerated under normal conditions, for then the throttle would be opened slowly a little at a time.

It has been suggested that the spring on the accelerator pedal be so adjusted that the weight of the operator's foot is just balanced, but this is bad practice—even though it does mitigate the alternate opening and closing trouble—for the reason that it encourages the continual use of the accelerator Even with such a spring the operator's foot is bound occasionally to depress the pedal unintentionally and the trouble is not entirely removed. If the



Digitized by Google

spring is made still heavier considerable effort is required to maintain the pedal in the proper position, and while this may become uncomfortable after a time it is a better alternative than making the spring either too light or of just such tension that the weight of the operator's foot is balanced, for it discourages the use of the accelerator

There is another abuse which the accelerator augments, namely, the racing of the motor with the cut-out open in order to warn pedestrians and the drivers of other vehicles. It is such a simple matter to release the clutch and depress the accelerator that the practice grows apace to the detriment of machinery and the joy of the garageman who supplies the gasolene and oil. Perhaps it is just as simple to race the engine with the aid of the hand-operated throttle, but there is not the temptation, and besides the action that is necessary is not really is a valuable aid to operation, provided it is properly used—used as it was originally intended and as it now should be intended to be used—as an auxiliary device and not as the main throttle control.

But to get back to the question of accessibility; it stands to reason that the better the driver and the more experienced he is the quicker and the harder he will jam his foot down in the region of the brake pedal in an emergency. If the brake pedal is under his foot when it comes down all is well and good, but if, perchance, the accelerator, instead of the brake pedal, be in the line of action, then is disaster invited, for an emergency stop generally means that the cause is distant scarcely more than a car's length or two, and whereas instant application of the brakes would avert the collision acceleration of the engine instead is very nearly certain to result in damage to something or some one. As a matter of the accelerator be either between the pedals or else at the right of the brake pedal, if the clutch pedal is at the left. The manufacturers of English Daimler cars fit a small auxiliary pedal at the left of the clutch pedal, but it is not an accelerator, in the sense that the word generally is used. It is merely for opening an auxiliary air valve in the carburetter and is for use only when the car is being driven at speed in order to reduce gasolene consumption. It is operated by the left foot, but its position is such that it is impossible to use it except when the clutch is engaged. In other words, it cannot be used as an accelerator, pure and simple.

It would appear that locating the accelerator pedal to the right of the brake pedal in the usual arrangement is better than placing it between that pedal and the clutch pedal for the reason that it may be placed further away and be less liable to accidental

FOREIGN PRACTICE IN DESIGN AND POSITIONING OF ACCELERATORS

so automatic—it requires greater premeditation.

In gear changing, the pedal-operated throttle may be either an advantage or a disadvantage according to whether a change to a higher or a lower gear is made and the skill of the operator. But regardless of the experience of the operator, the accelerator should prove an advantage when changing "up" for then the engine speed automatically is reduced when the pressure on the pedal is released. But when a change to a lower gear is made the accelerator may prove a disadvantage, for then, according to all the tenets, the engine speed should be increased instead of decreased. However, even in this case an accelerator may be an advantage if it is properly used, for it affords an easy method of increasing the engine speed temporarily with the gears in neutral and the clutch engaged and the operator's free hand on the gear shift lever for a quick change.

The principal advantage of the accelerator, of course, is that it leaves both the driver's hands free to operate the steering wheel, the gear shift and emergency brake levers and the signaling device. From which it may be deduced that the accelerator cold fact, so very many drivers keep a foot on the accelerator at all times, that in that fractional part of a second when danger threatens, the instinctive movement to "brace" oneself for the expected shock rarely fails to take the form of downward thrust of the legs and there is small doubt that it is the resulting unconscious pressure on the accelerator that has meant the difference betwen life and death in more instances than the world ever will know.

Therefore if the accelerator were hard to get at, if it were in a position less accessible where it would require conscious effort for the driver to keep his foot on it, there would be less likelihood of accidents of the kind. In the majority of cases, as may be seen by the accompanying sketches, the accelerator is placed centrally between the clutch and brake pedals, the purpose being to eliminate the necessity for very extensive movement in shifting the foot from the brake pedal to the accelerator, or from the accelerator, where the foot usually rests, to the brake pedals. For obvious reasons the accelerator always is operated by the foot that operates the brakes. Sometimes it is the left foot, but generally it is the right. Consequently it is necessary that pressure. Quite a number of manufacturers have embraced this arrangement, viz., White, Mercer, Chalmers and several others. Some of them place the accelerator quite a distance from the brake pedal and others locate it where it is possible to depress both the brake pedal and the accelerator at the same time by merely sliding the foot half off the brake pedal. In Pierce-Arrow cars, however, though the accelerator is placed between the pedals, the likelihood of its being pressed accidentally is reduced by the simple expedient of placing it several inches nearer the seat riser than is usual. In this way, also, its use is discouraged to a certain extent, for it is high enough to cause slight discomfort if it is used for extended periods.

But even when the accelerator is so far from the brake pedal that it is impossible to operate both at the same time, with the same foot, the fact remains that the operation of the device merely requires a straight downward push. Whether the operator's "foot slips," or he makes a mistake, or it is merely an instinctive bracing makes no difference to the operation of the accelerator. And though it may be held that no experienced driver would put on the brakes

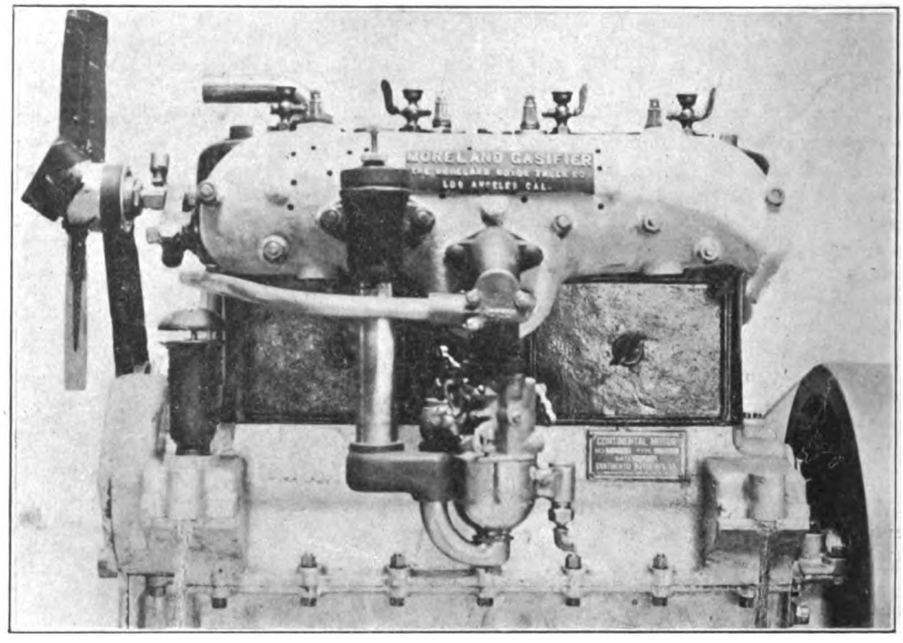
Digitized by Google

without first releasing the clutch, in which case it would make no difference whether the accelerator pedal were depressed or not there is no telling what anyone may do under stress of excitement and there is always the chance that the wrong thing may be done.

Without doubt, the most obvious way out of the difficulty is to eliminate the accelerator, but there are so many persons who use the device continually and have become accustomed to it that it is a question whether that course would be approved The accelerator is not an absolute necessity as far as that goes, and it could be dispensed with. As a matter of fact there is any number of drivers who never use an accelerator; they have no trouble getting along without it and they don't take anybody's dust on the road. It is not an uncommon sight to see a "green" driver, fresh from some pseudo-school, where old cars minus accelerators are used for instruction, attempting to drive with an accelerator. It requires knack to use an accelerator properly, which may acount for some of the mistakes that are made.

Another way out of the difficulty, though it is one that very few manufacturers have embraced despite its evident advantages from every point of view is to so construct the pedal that a sideways movement instead of an up and down movement operates the throttle. This reduces the danger of accident more than 100 per cent. in one fell swoop, for no amount of downward pressure, such as might be exerted spasmodically or by accident will open the throttle one iota. Incidentally, the operator's foot rests on the floor of the car and not on the pedal, and he may brace himself to his heart's content without altering the throttle opening. Another advantage of this arrangement is that for ordinary touring the operator is not constrained to maintain his foot in strained position and no amount of jouncing will affect the throttle opening. Notwithstanding these advantages, the manufacturers who have adopted this arrangement are few and far between. Overland cars are made this way and so are Pathfinder cars, and these two would seem to occupy the field alone, though some of the Chalmers cars last year were so equipped.

Barring the swinging accelerator, which certainly is the most logical type, according to the opinions of not a few persons who have driven cars equipped with both types, it seems that the only way out of the difficulty is to place the accelerator so that it must be stretched for—to place it where its promiscuous use will be discouraged and where it will be out of danger of being accidentally "stepped on." As it is, it is necessary for the driver to reach for the brake pedal, providing he drives with the accelerator entirely, as most drivers do, whereas it ought to be just the other way about; the driver's foot should repose on the brake pedal at all times, and it should be necessary to stretch for the accelerator.



SAVING OF 60 PER CENT. IN FUEL

Claim Made for California Gasifier Designed for Trucks—Uses Distillate but Needs Gasolene for Starting.

As the price of gasolene mounts, and it might be said in parenthesis that it is expected to continue to mount for some time to come, the search for some method whereby the cheaper and heavier hydrocarbons may be employed to advantage goes forward. Kerosene always has beckoned the inventor on in a disconcerting way, and though its use for stationary, constant speed engines has been brought to a point where greater success is obtained now than ever before, the fact remains that its employment for movable, variable speed engines without the use of gasolene as an adjunct for starting and heating up still is a problem that so far has defied solution. Nevertheless, the use of these two fuels in conjunction, though offering certain disadvantages, still offers advantages that cannot be overlooked, inasmuch as it is quite possible to effect considerable economy of operating expense in this way.

Recently, however, not a few manufacturers have turned their attention to the utilization of even heavier fuels than kerosene, and though the same disadvantage of having to use gasolene to generate the heat necessary for starting purposes obtains, results which have been achieved would seem to indicate that the added complication is more than offset by the saving in fuel cost which may be effected. In the case of the Moreland Motor Truck Co., of Los Angeles, which is the first company to undertake the manufacture of commercial vehicles on the Pacific Coast, and whose Moreland Distillate truck was illustrated and described in the March 7th issue of the Motor World, a saving of no less than 60 per cent, in operating fuel cost is guaranteed.

This great saving is effected, it is stated by the company, by the use of what is styled California No. 1 engine distillate, which is obtained from asphalt base crude oils. It sells in Los Angeles for seven cents a gallon, as against 16 cents for gasolene and tests out at about 52 degrees specific gravity. Furthermore, it is claimed that a gallon of distillate will operate a truck approximately 20 per cent. further than will a gallon of gasolene, for the reason that distillate contains the equivalent of 28,000 British Thermal Units to the pound, whereas gasolene of the usual grade contains only some 20,000 B. T. U.'s.

MORELAND GASIFIER APPLIED TO A CONTINENTAL MOTOR

In its simplest aspect—and it is delightfully simple—the Moreland Patent Gasifier, which is the device that makes possible the use of the heavier fuels—any liquid hydrocarbon from gasolene to kerosene being used with equally good results—consists of a cast jacket which surrounds both the intake and exhaust manifolds. The carburetter of the engine is fitted with a two-way cock and a small auxiliary tank of gasolene is used for starting, one gallon having been found to suffice for several days. Soon after the engine has started and after it has run long enough to heat the exhaust manifold, the gasolene is shut off and the distillate turned on. Short stops do not necessitate that the engine be restarted on gasolene, as the jacket of the Gasifier retains its heat for long periods. Though it might be supposed that the heavier fuel would cause carbon deposits and excessive smoking, it is explained that carburation is so complete that these difficulties are practically overcome.

TAXICABS NEED NOT LOSE MONEY

Right Cabs and Right Management Make Profits—Barker Enumerates Several Notable Instances and Gives Figures.

Much has been said and as much written on the subject of the expense of operating taxicabs, and if an average were struck, so to speak, of the opinions expressed the inevitable conclusions would be that making a profit from a taxicab service is not a little like the proverbial squeezing of blood out of a stone. But though unprofitable taxicabs are all too common, they are not by any means the only kind, according to John G. Barker, of the the Franklin Automobile Co., who has very distinct views of his own on the subject, and does not hesitate to express them. Barker particularly refers to the Pittsburgh Taxicab Co. as a concern that proves his contention that taxicabs do not have to be money losers.

"This company," said Barker recently, "operates 45 motor cabs, and is unique in that its operation is in charge of a firm of public accountants, who receive all of the fares collected by the drivers, make all disbursements and render a statement each morning of the preceding day's business. By systematic management this company has held its operating cost down to 31.6 cents per mile, including chauffeurs' commissions, tire mileage, depreciation, insurance, repairs, rent, garage wages, office salaries, taxes, licenses, executive salaries, telephone and every possible expense that can be figured against the service. The average tire cost with the Pittsburgh company is about three cents per mile, and the cost of operating taxicabs in Pittsburgh is probably as great as in any city in the United States, owing largely to the fact that its hills are many and steep.

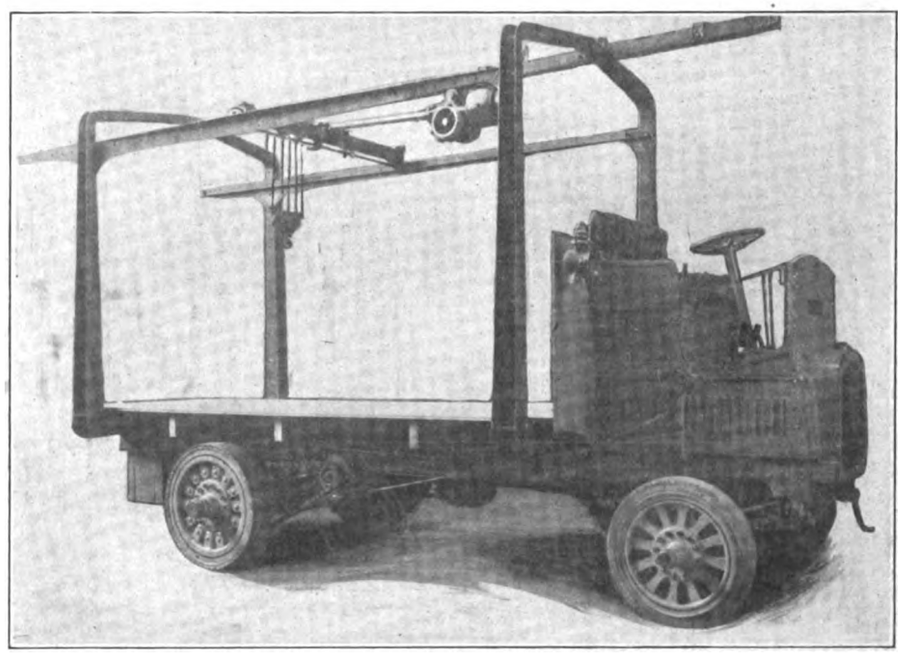
"That isn't the only one," continued Barker, "there are others. A concern in Brooklyn cleaned out an equipment of cabs that had proved unprofitable and made a fresh start with a new fleet. The initial payment on the new cabs absorbed the new capital brought in, but within two years the earnings had paid for the new machines and furnished working capital during that period as well. A few months ago a New York company started with five cabs, then added six and now is adding five more, all the money required for the purchase of the machines having been derived from the earnings of the cabs.

"If you want actual figures, there's a man in Boston who started a taxicab business only last November and already has it on a paying basis. He claims to get an average of 11.1 miles per gallon of gasolene and 312 miles per gallon of lubricating oil; his tires cost him 2.2 cents per mile, and his cabs cover an average distance of 47 miles per day.

"There's a Denver company, though, that has the best record I know of for economical cab operation, for it actually manages to keep all expenses—driver's salary, tires, oil, gasolene and all the rest of it—down to 13 2-3 cents per mile."

Not a few smaller cities are blessed with taxicab services that are in the money-making class, according to Barker, and in some instances the vehicles are required to run considerable distances into the suburbs of their respective towns.

These statements are of peculiar interest, in view of the somewhat gloomy financial aspect of the taxicab business in general, and while the vehicles employed in the services referred to by Barker are Franklin cabs, this does not in any way alter the fact that there is money in taxicabs that are sufficiently light and springy to be easy on their tires and sufficiently economical in their demands for gasolene, oil and repair parts to leave for profit at least part of the fares collected.



Unusual Excuse For Truck Drivers' Arrest.

The ways of the New York "cop" often are past understanding. Because a Pierce-Arrow demonstrating truck did not "bear sufficient evidence of hard work to warrant carrying a manufacturer's license" one of the bright bluecoats arrested the driver, Frederick Kurtz, and both driver and truck endured three days of enforced idleness before explanations could be made to a Brooklyn police justice, who dismissed the charge. The Automobile Dealers' Association of New York is so much incensed that it has laid formal complaint before the Police Commissioner, alleging unnecessary officiousness on the part of the arresting policeman, and emphasizing the loss of three days' work by the truck and driver, which complaint may or may not convey understanding to the "force."

TRUCK WITH A TRAVELING CRANE

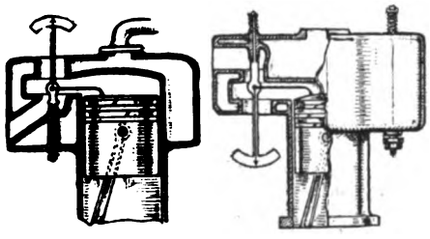
French Manufacturer Brings Out Unique Device for Facilitating Loading—Storage Battery and Motor for Power.

In appreciation of the fact that the successful operation of motor trucks on a paying basis necessitates that their efficiency as so much machinery depends to a great extent on whether or not they are maintained in constant use with as short periods of inactivity as is possible, the manufacturers of Delahaye trucks, which are products of French extraction, have evolved a unique auxiliary loading device

DELAHAYE TRUCK WHICH EMPLOYS AN ELECTRIC TRAVELING CRANE

in the form of a traveling crane. Winches operated either by hand or by the engine of the vehicle are not scarce, of course, and long since have proven their worth in facilitating loading and unloading, though so far as is known this is the first time a power operated traveling crane has been installed for the purpose of shortening the stops enforced when the truck must be loaded or the load discharged.

The truck on which the crane is mounted is a standard five-ton model and differs in no way from other five-ton trucks of the same make, except for the addition of the auxiliary machinery. It is driven by a gasolene engine in the orthodox manner, which is to say power is transmitted to the driving wheels through the intermediary of a selectively operated change speed mechanism and side chains. Differing from ordinary construction, however, the rear wheels which support the greater part of the load are shod with steel tires; the front wheels are equipped with rubber tires.



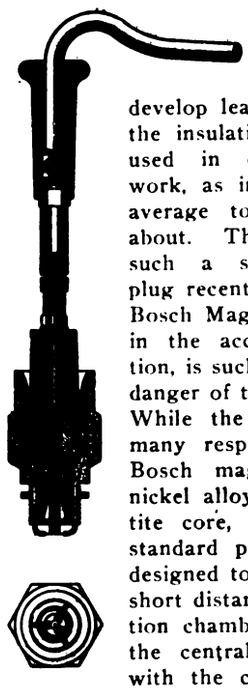
The crane is supported by means of channel section girders of inverted U form, the

Digitized by Google

traveler being mounted on side rails that are riveted to the side girders and thus serve to brace the whole. Power for the crane is obtained from an electric motor which drives through a worm gear and is carried by an overhead longitudinal track of such length that merchandise may be lifted from the road at the rear of the truck and deposited close up to the back of the driver's seat if necessary. The load that is lifted by the crane may be moved both transversely and longitudinally by means of the motor, the source of current being a storage battery of fairly large capacity that is carried in a receptacle at the rear and below the platform of the body.

For Indicating the Dead Center.

To determine the dead center point on motors with centrally located plugs needs but the insertion of a rod or stick through



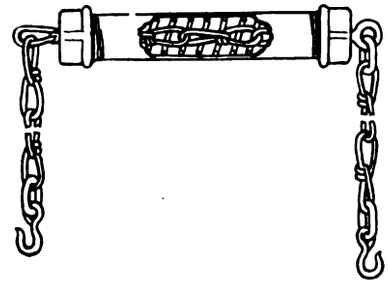
the spark plug hole, a turn of the fly wheel and a watchful eye. The usual method, where the spark plugs are located over the valve pockets, however, is to partially close the pet cocks and listen to the "wheeze." It is obvious that the latter method is rather crude and not productive of the best results, and certainly not accurate enough to be relied on if the valves are to be timed. In the effort to remedy this lack a very simple "dead center" indicator has been devised abroad for use in motors where the only access to the piston is through the port. As shown by the accompanying illustrations, the contrivance consists of nothing more complicated than a bell crank lever, one leg of which protrudes through the port and touches the top of the piston, while the other forms the indicating needle. The lever is pivoted to a stand bearing a quadrant over which the needls travels, and also provided with a stem which passes through the valve stem guide, where it is fastened by means of a nut and coil spring. The weight of the lever which touches the piston serves to keep it in constant engagement with the piston so that the slightest movement is indicated. The indicator can be used with the needle pointing either up or down, as the pictures show.

Handy Means of Reducing Fractions.

By way of alleviating the troubles of those who have occasion to reduce common fractions to decimal fractions the Standard Roller Bearing Co., Philadelphia, Pa., has gotten out and is distributing a handy little celluloid conversion table of the "clock" pattern. It is square, to fit the vest pocket, and the decimal equivalents of common fractions appear on a circular disc in red through "windows" in the outer casing. Any decimal equivalent from 1-64 up to 63-64 can be ascertained quickly and easily by merely turning the center circular disc until the common fraction and the decimal appear at their respective "windows."

Bosch Sprak Plug for Heavy Duty.

Spark plugs used in heavy duty motors that are expected to run for long periods without stopping, or in motors having high compression, or under other conditions of more than usual severity, are more liable to become overheated and to develop leaks and trouble with the insulating core than plugs used in comparatively light work, as in the motor of the average touring car or runabout. The construction of such a special heavy duty plug recently developed by the Bosch Magneto Co. and shown in the accompanying illustration, is such as to minimize the danger of trouble in such cases. While the plug is similar in many respects to the regular Bosch magneto plug, having nickel alloy points and a steatite core, it differs from the standard pattern in that it is designed to project only a very short distance into the combustion chamber. The flat end of the central electrode is flush with the crescent-shaped ends of the side electrodes, and, owing to the comparatively small area exposed to the heat, it is claimed that the points will not fuse under any conditions of service, the heat being conducted away fast enough to keep them adequately cooled. As in the regular Bosch plug, packing is effected by means of copper gaskets. A hard rubber protector receives the end of the high-tension cable, protecting the bared end of the wire and also supporting the cable where support is most needed. A set screw is provided to clamp the wire to the terminal, a fastening which is at once simple and secure.



Relation of Float and Float Chamber.

The relation of the size of the float to the size of the float chamber is a matter of more importance than appears at the first glance. If a carburetter is detached from the motor and the chamber filled with gasolene, a sudden movement will, owing to the inertia of the liquid, cause a certain amount of movement of the float, which movement will cause the admittance of more fuel, raising the level in the float chamber above the top of the jet. The same thing happens when the carburetter is placed on the motor and the car is traveling over rough roads, and choking and irregular running are the results. The remedy is suggested by a practice which is common among seamen to prevent "slopping" of a water contained in a pail and consists of placing on the water a circular float of very near the diameter of the pail. The inertia of the float counteracts the inertia of the water and the level of the water is preserved. If the carburetter float were made large enough nearly to fill the chamber very much slopping would be prevented.

To Ease the Shocks When Towing.

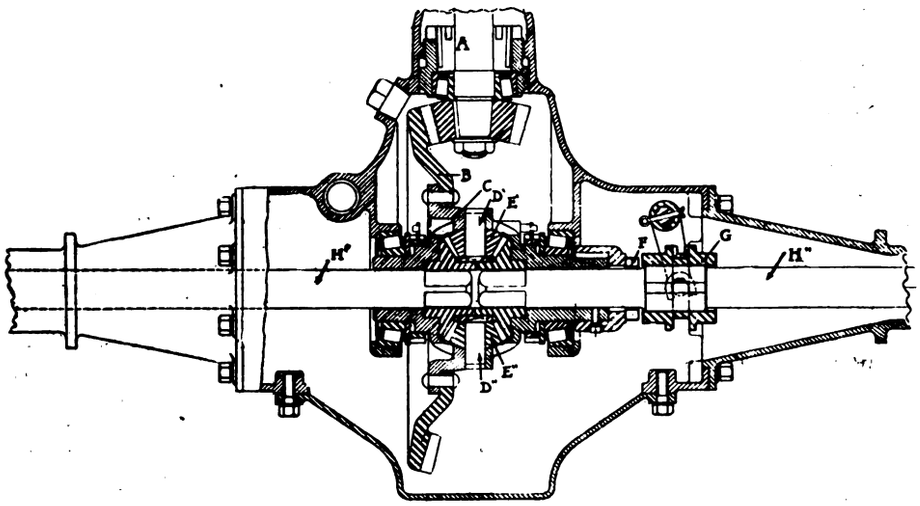
Towing a disabled car is an unpleasant job at best, and the task is not made any easier by the sudden jerks that usually are unavoidable, and which sometimes are the cause of bent or strained parts. With a view of preventing trouble of this kind, the Auto Towing Device Co., of Cleveland, O.,

has brought out the "Jarless" towing device. This consists of two chains connected together by a sort of spring buffer—a cylindrical metal casing containing helical springs which are compressed under a pull and ease the shock of a sudden start. The chains are stout and strong, and two hooks are fitted for attachment to towed and towing machines; a swivel joint is provided, so that if the chain is accidently twisted it will straighten itself out. The total length of the chain and spring is 15 feet.

Simple Method of Filtering Oil.

Where the pennies are watched, a saving in the yearly lubricant bill can be effected if all of the oil which periodically is drawn from the crank chamber of a motor is filtered and re-used. A simple method of filtering, and one which is effective, is to place the dirty oil in a bowl and position a length of lamp wicking so that it will reach from the bottom of the bowl and over its side so that the wicking will conduct the oil into another receptacle and leave the dirty residue behind.

Radiator Caps That Require Care.



There are not a few manufacturers who now fit radiator caps that fasten with clamps or else crew on with good, heavy threads, but there still are some whose radiator caps have regular "optical instrument" threads that are hard to start and that jam so easily as to be a nuisance, to say nothing of the ease with which they get crossed. The only thing to do is to take time and care to put the cap on properly and avoid spoiling the thread.

DIFFERENTIAL LOCK CONDEMNED AND DEFENDED

Its Functions and the Manner in Which it Operates Made Plain—Havoc its Use May Work Unless Proper Precautions are Taken in Designing—Engineers' Opinions for and Against the Device That Reveal its Present Status.

When winter weather gives way to spring and under the influence of April showers roads, which during the "off season" have been neglected, become near-morasses, it is a comparatively common sight to see a heavy motor truck stalled in the mud, one wheel on terra firma and the other revolving idly and churning up the semi-liquid real estate. Much the same occurrence takes place often enough when there is snow or ice on the ground and only one driving wheel "bites" the road. Under such circumstances, however, it is a comparatively simple matter to move the vehicle a little by means of levers until both wheels exert the same tractive effort, though in mud, or sand, it is quite a different matter, as the idly revolving wheel digs a pit for itself in a short time and conditions become still more complicated.

PLAN VIEW SHOWING DIFFERENTIAL LOCK AND ITS OPERATION

All of which is due directly to the action of the differential gear. The differential has been described as a necessary evil; there is no doubt but what it is a necessity and also that it is an evil under certain circumstances. As every one who is even remotely acquainted with automobiles for either pleasure or commercial purposes knows, a self-propelled road vehicle cannot exist without some means of equalizing the driving effort on both driving wheels at all times. For instance, when a vehicle is rounding a corner, the outside wheels travel in the arc of a circle of great radius than the radius of the circle on which the inside wheels travel. Consequently the outside wheels travel a greater distance than the inside wheels, though the unit of time is the same. Therefore it is impossible to connect the two driving wheels solidly together and apply the power in the same proportion to both of them, for they seldom rotate at exactly the same speed. There always is a certain amount of relative movement between them. It is the purpose of the differential gear, or balance gear, or equalizer, the terms being practically synonimous, to permit this relative movement while at the same time causing the driving strain to be balanced between the two wheels at all times.

Unfortunately, however, differential mechanisms are not as perfect as they might be. That is to say, the mechanism is just about as perfect as it is possible to make it in its present form, but that this form really requires revision—that the attainment of the desired ends should be accomplished in some other way—is a matter which scarcely requires enlargement. As has more than once been advocated, the type of differential that is desired is one that will compensate for distance and not by distance. But until such a mechanism is devised, and recent attempts which have been made lead to the optimistic conclusion that the solution of the problem is nearer hand than generally is supposed, it remains to get along with existing types and to adapt them to the work in hand, in so far as is possible.

Though the action of the differential gear is fairly well known, it may not be irrelevant, by way of assisting in the explanation of the action of the differential lock, to interpolate a short description of the functions of the differential and the manner in which it operates to equalize the driving strain. The differential may be likened to a beam suspended by means of a rope attached at its center; it is to be assumed that the beam balances. If an equal pressure be brought to bear on both ends of the beam, a straight pull up on the suspending rope will result in the beam being moved upward though its relationship with the suspending rope will not be altered. Which is to say, that it still will remain horizontal and parallel to the earth. But if either end of the beam be anchored so that it cannot move, the beam being as a lever of the second class, having equal arms, the other end will move through twice the space in the same time that it would under ordinary circumstances with the same pressure acting on both ends. A familiar example may be found in the whiffle-tree as commonly used on wagons that are drawn by a team of horses, its object being to equalize the pulling power of both animals.

The differential as used in automobiles is, of course, vastly more complicated than the simple suspended beam or the whiffle-tree, though the principle involved is exactly the same. Thus, for instance, if one driving wheel of a vehicle rests on a dry, hard surface, in which case the traction obtainable is at the maximum, it then becomes as the anchored end of the suspended beam. If the other wheel is on a slippery surface it becomes as the free end of the beam and consequently rotates at twice the speed it would if both wheels were on equally hard and dry surfaces. Which, briefly, makes plain the shortcoming of the present-day types of differential gears. As long as the traction obtainable at both wheels remains greater than the tractive effort put forth, the differential acts as an equalizer or a balance gear and the power available is proportionately distributed between the two wheels. When one wheel loses all traction, however, the differential is no balance gear, as it then permits all the power to be transmitted to the one wheel which is rotating idly, the other wheel at which traction is available remaining, to all intents and purposes, dead. Consequently, what is desired is a differential gear that will act to equalize the driving strain on both driving wheels under every condition and all conditions of road surface.

So far, no such mechanism has been developed, at least to the stage where it is of commercial value, though, as has been stated, numerous attempts have been made,

Digitized by Google

and it is not unlikely that eventually a solution of the problem will be forthcoming. In the meantime, as a differential gear of some sort is absolutely essential, the shortcomings of present-day types must be overcome and it is the purpose of the differential lock to overcome the prime fault that just has been outlined.

As the name of the device indicates, its purpose is to lock the differential, or, in other words, to cut it out of operation temporarily in order that all the power may be applied to either of the driving wheels which may be on hard dry road when the other wheel is on a slippery spot. The locking of the differential has the same effect as would be obtained if in the example of the balanced beam suspended at its center two braces were placed between the ends of the beam and the point from which the beam was suspended.

It is but natural that each manufacturer should have his own particular method of locking the differential mechanism. The principle remains exactly the same in any case, however, and is made plain by the accompanying cross-sectional picture, which shows a lock with its relationship to the rest of the differential mechanism.

In the drawing, the propeller shaft is designated A and the driving shafts as H' and H". B is the bevel driving wheel, and it drives the differential pinions E' and E" through the pins D' and D", which are mounted in the cage C, to which the bevel drive wheel is bolted. The driving shafts (H' and H") are not connected to the inside differential cage (C) in any way, but are free to rotate in it. They are driven by means of the horizontal pinions, which mesh with the pinions E' and E". Consequently, if the traction at each driving wheel is the same the pinions in the differential remain in their relative positions and the whole cage (C) rotates as a unit, imparting the same motion to both driving shafts. If, however, one of the driving shafts is maintained stationary, as it would be if one wheel only was on hard, dry road, and the other was on a slippery spot, then the pinions E' and E" (there are four of these pinions, though only two of them are shown in the drawing) would roll around the pinions to which the stationary shaft is connected, and in doing so would multiply by two the movement imparted to the other drive shaft.

It is in preventing this relative movement betwen the two driving shafts that the differential lock serves its purpose and the method of preventing the movement is as simple as it is efficacious: The lock is simply a sliding sleeve (G), which fits over a squared portion of the driving shaft (H") (it would operate exactly the same no matter which of the driving shafts it is on) and engages with teeth (F) on the end of the differential cage (C). When the sleeve is moved up into engagement with the teeth on the differential cage one driving shaft is locked fast to the cage, and as relative movement between the pinion into which the driving shaft fits and the pinions E' and E" thereby is made impossible it follows that relative movement between the other pinions also is impossible. Consequently the two driving shafts are locked together and rotate as one. As has been previously stated, there are several other methods of locking one of the driving shafts to the differential cage, though the ultimate effect obtained is the same, regardless of the system in use.

The purpose of the differential lock already has been explained, but despite the very evident advantages of the device under certain circumstances not all manufacturers incline to its use. Opinions as to the actual value of the device are divided; some automobile engineers decry its use in no uncertain terms, while others, some of whom have equipped their vehicles with it for a long term of years, speak very highly of it and state that they have no fault to find with its operation.

Cornelius T. Myers, who is chief engineer of the General Motors Truck Co., Detroit, Mich., is one of those whose damning of the device does not even take the form of faint praise. "A differential lock was tried on several of the General Motors Co.'s trucks," says Myers, "but it was dropped. It was found not only an unnecessary complication, but a dangerous one. It also greatly adds to the weight of the parts affected by its operation. Not only must any standard size countershaft for a given horsepower be doubled in size in order to take the total engine torque when one wheel is slipping and the differential is locked, but one should really also redesign the mental functions of the driver. This is not intended as a reflection upon drivers, as will be seen from the following:

"The differential was devised and installed for the purpose of supplying compensation between two driving wheels; it is absolutely automatic in its action. The locking of the differential removes this automatic function and in its place is left the judgment of the driver to determine exactly when the relative rotations of the wheels require compensation and to unlock the differential lock at that precise, particular moment. If he does not act as promptly as the differential itself would act, breaking tendencies are set up in all the parts affected and the tires will have a tendency to tear off. When any of these things actually do happen, the driver unjustly gets the blame."

"No human intelligence is sufficient for the task of unlocking the differential always at the scientifically correct moment," Myers sums up the situation, "and any moment less than scientifically correct makes the lock too dangerous for a careful manufacturer to sell to a confiding customer."

All of which is interesting as coming from a man who undoubtedly has had a great deal of experience in the designing and construction of commercial vehicles. However, despite the pithiness of Myers's remarks, several of the statements require slight modification, for it should be remembered that the differential lock is a device which is intended for use primarily in emergencies and only for very short periods. Though it has been suggested that the differential lock serves one of its most useful purposes in permitting a truck to be driven with one chain broken when the truck ordinarily would be hors de combat unless the driver was supplied with repair parts, such use of the device scarcely can be advocated for the very reasons that Myers points out. No matter how smooth the road may appear to the driver, nor how straight a course he may imagine that he is pursuing, his judgment may be at fault. Every time one wheel mounts an obstruction or drops into a declivity—no matter how slight the obstruction may be or how shallow the declivity—then that wheel ordinarily would travel a greater distance than the other wheel, which rolls over perfectly smooth road, provided the differential were in operation. It is the purpose of the differential to permit this relative motion between the two driving shafts as already has been pointed out. It stands to reason that when the movement is not permitted there must be set up a certain strain that would not be present with the differential in operation—a strain on both the transmission mechanism and the tires.

Naturally, in those vehicles in which a differential lock is employed the affected parts are made slightly heavier in order to offset the extra strain which is placed on them when the differential is locked. Whether or not the amount of great weight which is necessary is a greater detriment than the presence of the differential lock is a convenience is an open question. At any rate, Mortimer Roberts, chief engineer of the American Locomotive Co., Providence, R. I., is of the opinion that the differential lock is an excellent device and he is not alone in his view.

"The assertion that the lock is in any way dangerous," Roberts says, in reply to a letter of inquiry from the Motor World, "in my opinion is absolutely unfounded. We certainly do consider the differential lock of great value. We have used one for over four years and have yet to hear of any broken chains or shafts caused by its use, so far as the Alco trucks are concerned."

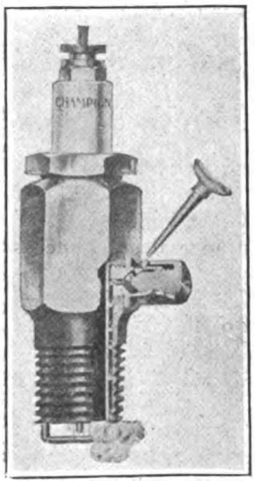
Henry H. Hower, of the F. B. Stearns Co., Cleveland, O., writes in much the same strain and commends the device highly. "Our experience with and without a differential lock on the transmissions of our trucks which we have had in service at our factory the last three or four years," Hower writes, "would indicate that while the number of occasions on which a differential lock is of use is very slight, yet when needed it is a feature that is very desirable, to say the least. In such instances such a lock would ofttimes eliminate the necessity of a tow. We have never had occasion to use the differential lock in order to drive on

Digitized by Google

but one chain, but we have used it often in transmitting the power to the one wheel which had traction. And in the ability to do this we believe lies the chief value of a differential lock.

"In regard to the objection to its use, due to unnecessary complication and design, and to added weight, and to danger of its use by inexperienced operators, we do not believe that anf of these objections apply to the device as we design and equip it. The added complication of a sliding jaw clutch mounted on one of the differential shafts and clutching this shaft positively to the differential sleeve is not very much, since it requires but the addition of two pieces in the transmission, viz., a clutch and shifting finger, and on the outside of the transmission a connecting link and operating lever. The weight of these parts is extremely slight, and is a very small addition to the weight of the truck chassis."

Similar views are held by the Velie Motor Vehicle Co., Moline, Ill., and a number of other manufacturers who have had considerable experience with the differential lock as an adjunct to the operation of their vehicles. This does not alter the fact, however, that there is a possibility that any driver may forget—no one is infallible—and leave the differential locked when according to all precepts it should be unlocked and in working order. Nevertheless, not all manufacturers have kept this idea in mind in equipping their vehicles, and it is not unlikely that part at least of the "black eye" which the differential lock has received from some quarters is due to this.



In Velie trucks, however, the engineers have evolved a design which makes it impossible for the driver to maintain the differential locked without a conscious effort. Its use therefore is discouraged except in case of necessity, and the likelihood of its being inadvertently left locked is minimized. This very desirable end has been attained by the simple expedient of actuating the differential locking mechanism by means of a spring-returned pedal. It is necessary for the driver to keep the pedal depressed the whole time the differential is to be maintained locked; immediately the pressure on the pedal is released the differential automatically unlocks itself.

Similar methods are in use on a number of other trucks but the designers of Stearns vehicles have attacked the problem from an entirely different angle. The Stearns differential lock is worked by means of a lever which operates in one of the slots of the change speed lever quadrant and is so arranged that when the differential is lyocked the lever is in such a position that it is impossible to engage any other speeds than low speed ahead and reverse. Similarly, it is impossible to lock the differential when any gears other than these two are in use.

The lock often has saved the expense of a tow and has increased efficiency by reducing the time during which the truck was inoperative. Nevertheless, it is essential that the necessity for the maximum degree of "foolproofness" be kept in mind, and though the differential lock undoubtedly adds slight complication—complication which is so slight as to be practically negligible—the "human element" in the equation should not be forgotten and the manipulation of the device should be so regulated that its use is discouraged except for emergency, and it should positively, and automatically, unlock itself the instant its temporary usefulness is over.

Spark Plug That Permits Priming.

When a motor is very cold and therefore difficult to start, priming the cylinders by the injection of gasolene not infrequently fails to bring about the desired result because the vapor of gasolene, being heavier than air, settles down at the point furthest from the spark plug, and the combustible vapor does not come within reach of the spark. As in such a case the plug cannot well go to the gasolene, the Champion Spark Plug Co., of Toledo, Ohio, has hit upon the idea of bringing the gasolene to the plug by making a priming plug in which the gasolene when injected passes close to the sparking points and offers the best possible opportunity for the spark to ignite it. If there is any warmth in the plug the liquid is likely to expand considerably as it emerges, thereby increasing the chances of ignition. A needle valve in the side of the plug provides a means for injecting gasolene; the arrangement is shown in the accompanying illustration. A cap screws over the valve lug and when screwed all the way on covers the gasolene inlet, while a central tapered plug closes the passage and prevents leakage from the cylinder. The motors of the Ford cars, which are without separate priming cups or provision for their use, are fitted with Champion priming plugs, which recently were placed on the market, as standard equipment.

CHAMPION "PRIMING" PLUG

About Soldering the Ends of Spokes.

Although it has been suggested that the loosening up of wood wheels may be prevented by filling all spaces around the ends of the spokes and in the felloes with melted solder, it is by no means advisable to try such a plan, as the heat of the metal is sure to cause a certain amount of shrinkage of the wood, and the metal itself shrinks in cooling, so that the spaces cannot be properly packed in this way. A wheel that has shrunk through dryness until it is loose can be tightened up by wrapping wet rags around the ends of the spokes, both at the rim and at the felloe, taking care that water is not allowed to get under the tire. An occasional application of this sort will keep wooden wheels perfectly tight in the driest weather.

Spark Plugs and Engine Starters.

A little extra attention should be paid to the spark plugs of a motor employing an automatic starter, mainly because the efficiency of the starting device depends largely upon the ignition, and if the plug is sooted up it is not unlikely to fail to give a spark of the requisite intensity. There are those who believe that the combustion of acetylene has a tendency to add something to the deposit of carbon, and this would of course lend additional urgency to the necessity for keeping a sharp eye on the plugs. When a starter fails to set the engine going, it is a safe rule to examine the spark plugs. One fouled plug often is the cause of the difficulty.

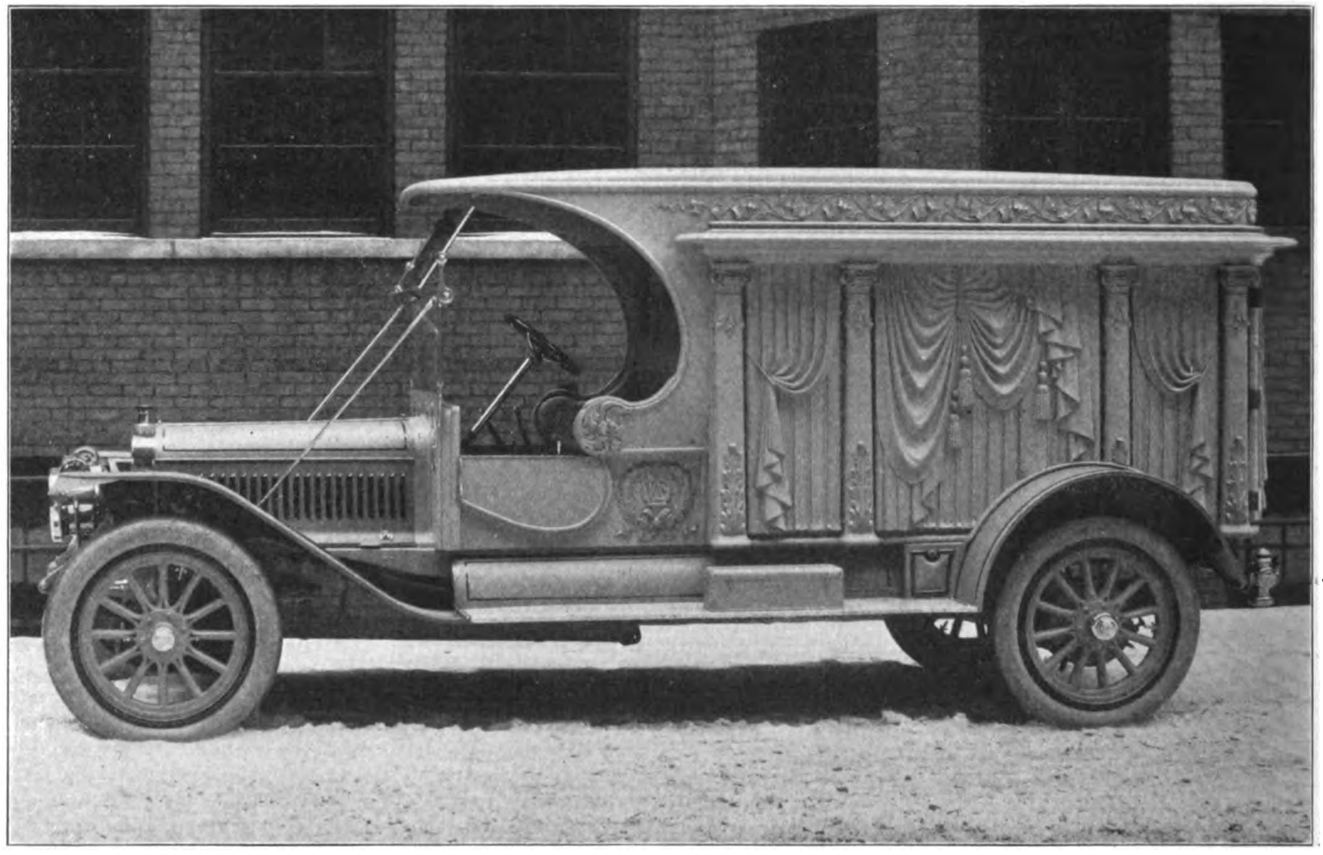
Waste Indicated by Hot Wires.

Trying to force a heavy current of electricity through a wire that is of insufficient size is much like trying to force water through a pipe that is too small. In both cases there will be a drop in the pressure between the source of current and the point of delivery—the electrical pressure being the voltage—and there will be a waste of energy in overcoming the friction or its equivalent. In the case of electricity, however, the trouble at once makes itself apparent by the heating of the wire. A hot wire invariably indicates a waste of current, for it requires a certain amount of energy to generate the heat.

Effect of Water in Babbitting.

When babbitting bearings, or doing any other work requiring the pouring of melted metal, the greatest pains should be taken to see that there is no water, not even the smallest part of a drop, where it will be reached by the metal. The sudden expansion of the water into steam amounts to a small explosion which throws the hot metal about in all directions with results that easily may be serious.

Oil Pump Leak That is Vexatious.



If there is a leak in the suction pipe between an oil pump and the tank from which it draws oil, it will either fail to pump or will pump a smaller quantity than it should pump, taking in air instead of oil Careful examination is required to discover a leak of this kind.

TEXAS HAS HORSELESS FUNERALS

Dallas Undertaker Provides Motor Hearses and Advertises It, Too—"Hedges" So as to Suit Everyone, However.

While there unquestionably are phases of the undertaker's business that necessarily are of a deliberate character, it cannot be truthfully asserted that the funeral director of to-day is at all slow to avail himself of such aids to success as motor cars. On the contrary, there usually is some little difficulty in bringing the funeral-going public to see the fine points of the new order of things, and this fact has caused at least one wide-awake undertaker to "hedge" by providing two complete outfits, so that he is in a position to advertise—and does advertise—that his patrons can choose between funerals in which horses furnish the motive power as in the past, or corteges in which all the vehicles are motor propelled, including the hearse—true horseless funerals. Undertaker Loudermilk, of Dallas, Texas, is the man, and his hearse is cleverly built on a Winton six-cylinder chassis, the designing having been done so skillfully that the lines of the familiar hearse body merge, without shocking the eye, into the form made necessary by the motor car front, and the imminent danger of producing a vehicle having the appearance of a delivery wagon is avoided. The smooth, silent running of the Winton car makes it well adapted for this class of service. Incidentally, it may be said that the motor hearse forms the last link in a chain, for it now is possible for a man to smash himself up in a motor car, be taken to the hospital in a motor ambulance and, should the worst come to the worst, leave the hospital for his last motoring trip in a gasolene hearse.

WINTON HEARSE WHICH CONSTITUTES PART OF THE EQUIPMENT OF A TEXAS UNDERTAKER

English Notions In Electric Vehicles.

Apparently concerned by the rare probability of death suddenly overtaking the operator, an English firm, Macfarlane & Burge, of Chelmsford, have designed an electric vehicle in which provision is made for even that exceptional contingency. The handle of the controller being brought back to the braking position by the action of a spring when the hand of the operator releases it; in case anything happens to the driver the current thus is cut off and the brakes are set when the dropping hand releases the controller.

The operating and control systems of the vehicle embody several other more or less novel features, all of which have been tried out on electrics in this country with no extraordinary amount of success. Probably the braking entirely by means of regeneration of current is the most interesting feature, for not only are the usual expanding or contracting band brakes done away with, but the kinetic energy of the car is changed back into potential energy, which is returned to the battery in the form of current and stored for future use. The use of a controller of the series parallel type is dispensed with by the introduction of a so-called "motor booster," which limits the amount of current which can be taken from the battery. The motor employed is a specially wound shunt machine and the torque-speed characteristic is said to be similar to that of a series motor.

Old Felt Hats as Magneto Covers.

The suggestion from foreign source that an old felt hat can be converted into a magneto cover is all right as far as it goes, but it should be remembered that the felt, once wet, will hold moisture for an extraordinarily long time and may harbor dampness that will injure the magneto if it is left unused for any length of time. From the same source comes the tip that a smashed tail lamp can be temporarily replaced with an empty jam jar with a candle placed inside. The smudges of jam in the jar supply the requisite red color.

The Sampling of Battery Solutions.

In taking readings of the specific gravity of battery solution, care should be taken thoroughly to empty the syringe of the electrolyte from one cell before taking up a sample from the next, or the figures will not be correct.

CONDITIONS AFFECTING MOTOR TRUCK SERVICE

Why Motor Trucking Includes Much More Than Motor Trucks and Wherein Excessive Delays Can Neutralize the Efficiency of the Best Trucks — Horses and Horse Conditions Responsible for Much Dissatisfaction With Machines — Examples of Time-Wasting Methods.

It is a fact that in no wise detracts from the merit or the usefulness of the motor truck that the machine itself is only one of many factors that must be taken into consideration in determining whether mechanical transportation in any partcular instance is likely to be an economical proposition or the reverse. In other words, the motor truck is by no means all there is to motor trucking. It is not sufficient that the machine itself be a good one and adapted to the work it is intended that it shall perform. The conditions under which the machine works must be favorable, to some extent at least; the more favorable the conditions, the greater the economy realized from the work of the car, and on the other hand, the more unfavorable the conditions the smaller the economical margin, until the point may be reached where the machine will operate only at a loss, regardless of its mechanical efficiency and the proficiency of the driver.

The prime point of superiority of the motor truck over the horse-drawn truck—that it is capable of transporting freight for less money—cannot be realized, of course, unless the loading and unloading of the machine can be accomplished with a reasonable degree of promptness, and the runs to destinations and return made without unreasonable delays. As a rule the speed that can be made with even the slowest machine is much superior to horse speed, load for load, if nothing seriously interferes with the use of that speed. And it is a comparatively rare thing, though not unheard of, for a truck to be so hampered in its road work as to make it unprofitable, other conditions being of a fairly favorable character. It is evident, therefore, that the most likely causes of unprofitable truck operation are to be found at the loading and unloading points; observation and experience tend to prove that such is the case.

Great bodies are slow to move, and once in motion, it is a slow matter to alter their direction. This is at the bottom of most of the trouble that sometimes is experienced in making motor trucks pay, for the whole world is accustomed to horse haulage and all transportation arrangements have for centuries been worked out with a view to facilitating the use of horses. The conditions that are best suited to horses being in many cases very far from suitable for motor truck work, it follows that the motor truck often is badly handicapped, for not only is it endeavoring to change conditions, but it is trying to do so while horses still are in the very great majority, and horse conditions must, of necessity, prevail to a very great extent for some time to come.

There is one essential difference between motor trucks and horses that becomes painfully apparent when machines are worked under the control of persons who have become thoroughly imbued with conditions that govern the use of the animals, as is the case with most transportation men. The best thing that can be done with a motor truck is to keep it moving as much of the time as possible. There is nothing to prevent a good motor truck from running all day, continuously, outside conditions permitting; but it is essential that horses, especially if they are pulling up to their normal capacity, as is usual in these high-pressure times, should have some little respite between trips, and as a consequence a certain amount of delay at each end of the trip is not only beneficial, but is often absolutely essential, for horseflesh wears out with undue rapidity if pushed too hard. Thus it happens that there are a thousand little delays and time losses that form part of the existing transportation systems and that sorely irk the souls of the truck people because they keep the machines standing when they ought to be on the road earning money—or saving it, which is the same thing on the books.

As an example, the coal business may be mentioned as one in which horseflesh is pushed to its limits, and were it not for the delays that occur in loading and unloading the animals would give out far sooner than they do—which is soon enough, for five years is a long working life for a city coal horse. When a coal wagon is ready for a load in a busy yard it is more than likely that it will have to stand in line for some little time waiting for wagons ahead to get their loads and move on. While in some of the more modern plants chutes are so constructed and the supply so arranged that the loading is quick, ordinarily the process is rather slow, and sometimes it is drawn out by the approaching depletion of the pockets containing the coal. When the load is on it must be weighed, and if the driver's estimate as to weight was not a good one, coal has to be shoveled off or on, as the case may be, until the load is within the limit permitted—20 pounds per ton. After that the driver goes to the office to get his "ticket" or delivery slip, sticks it in his hat and ambles leisurely to his wagon and starts on his plodding way—if the horses do not need to be watered.

Arrived at his destination the horses stand and rest contentedly while the Jehu hunts up the janitor, or the engineer, or someone to sign the receipt, which must be done before the load is "dumped," and then proceeds to get the load off. This may be a simple process, or it may be the opposite. If the coal hole is near the curb, or within reach of the "pan" or wagon chute, and there is plenty of room below, and the coal runs freely, all is well; the load will be disposed of in short order. But in very many instances one or more of these conditions are not present. Coal holes are arranged with more reference to the convenience of the builders than of the coal dealers, and almost everyone has seen a coal chute stretched across the sidewalk to a hole far from the curb, the driver using a shovel or broom with vigor in order to coax the coal down the slight incline. Or it may be that even this is impossible and the coal must be "barreled" across the sidewalk, or wheeled away in wheelbarrows, and it is entirely possible to fully occupy an hour and a half in handling a load of five or six tons in this way.

Again, it is a common thing for the driver to descend to the coal cellar and crawl on his stomach over coal piled almost to the ceiling in order to reach the bottom of the coal hole and clear away the coal as it comes down, so as to make room for the load. It is nothing short of exasperating to put a motor truck at work that is delayed in this way and find that it is forced to stand idle perhaps sixty per cent. of the working day, when such idlness, which, of course, is not in any way the fault of the machine, is making the difference between success and failure. It is unfortunate, too, that motor trucks working under such conditions too often are judged—and sometimes condemned—solely on the basis of tonnage handled, without consideration of the reasons for unsatisfactory results shown on the weekly reports.

Obviously the remedy is not vested wholly in the owner of the truck, but is divided between him, the receiver of the goods and to some extent, the operator of the machine. As the Peerless Motor Car Company's truck department aptly expresses it: "Delays are costly not alone because they mean a tied-up investment, but because they rob the truck of an opportunity to create values—what the economists call place values—in excess of the

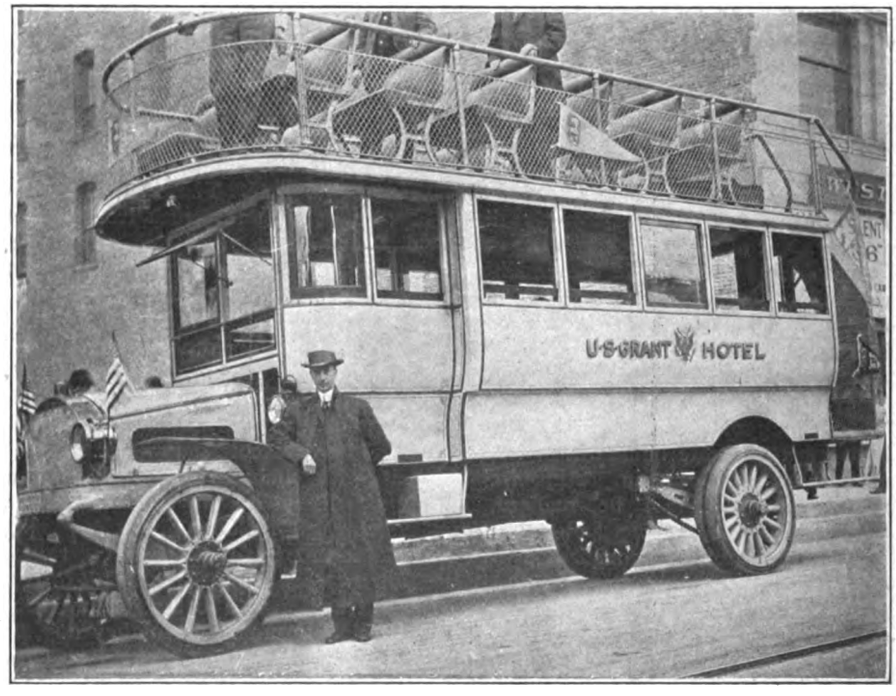
Digitized by Google

amount represented by interest on the truck investment. Successful co-operation in motor trucking is a three-cornered affair. It must include the shipper, the truck operator and the receiver, whether all three happen to be parts of a single company or are separately managed. The more complete the co-operation is the more work the truck will do and the greater will be its value."

While the coal industry furnishes a striking example of conditions that are difficult to overcome, it is by no means the only business in which machines are placed at a serious disadvantage and their usefulness unnecessarily curtailed. The same deliberation in loading and unloading and the same lack of facilities at both ends of the trip are found in nearly all classes of business. And the part of it that the truck maker or dealer feels most is that the man who buys a machine or makes use of one very often looks no further than the records of work done, and forgets—and often declines to be reminded of—the reasons why the machine failed to meet his expectations. In many instances the real source of trouble has been recognized and the obvious remedies applied, with such excellent results that a number of truck concerns now make a specialty of service departments devoted to the task of helping truck users to discover and eliminate conditions that militate against the profitable use of machines.

"Rubbernecks" Barred from Parks.

No longer will the voluble and leather-lunged megaphonist of the sight-seeing motor car expiate on the beauties of Central Park to his admiring passengers—unless he does it outside the confines of the big playground. New York's park commissioner has decided that the big machines are a menace to other vehicles on the park roads, and also that the passengers on some of the more elevated cars are in danger of being left hanging on the lower branches of the park trees; therefore the park police have been given orders to exclude the rubbernecks, and they are obeying orders to the letter. Section 19 of the park ordinance prohibits the use of the park roads by commercial vehicles and motor vehicles let for hire, and the sight-seeing wagons are classed under the latter heading. While taxicabs belong to the same class, both they and the sight-seeing cars have ignored the rule for so long that the commissioner's order was not at first taken very seriously, and it was not until a court summons was presented to a chauffeur of the Manhattan Sightseeing Co., who disregarded the rule, that it was realized that the commissioner was in earnest. Some months ago the sight-seeing companies, objecting to being shut out, took a test case to court, but as yet no decision has been reached, and in the meantime the big cars can do no better than skirt the edges of the park and let the sight-seers exercise their imaginations under the able stimulus of the elocutionist at the small end of the megaphone.



BIG BUS CARRIES FIFTY PASSENGERS

Built in Los Angeles and Claimed to be Largest in the World—Its Proportions and Features.

What is claimed by its builders to be the largest double-decked motor omnibus in the world has been built in Los Angeles, California, by the Western Auto-Body & Mfg. Co. for the U. S. Grant Hotel in San Deigo. The huge vehicle, the proportions of which are well shown in the accompanying illustration, has seating capacity sufficient for no less than 50 passengers, and and chassis, necessarily of the most substantial character in order to carry the great weight, is of the 5-ton truck type. Carrying passengers, however, and not inanimate freight, more than truck speed is demanded, and the power plant therefore is a big one, consisting of a 90-horsepower motor mounted in the conventional forward position under a hood; final drive to the rear wheels is by side chains. The length of the wheelbase gives a good idea of the hugeness of the double-decker, the distance from axle center to axle center being 192 inches—16 feet. The length of the machine over all is 28 feet and the height 12 feet 6 inches.

All seats face forward and are finished in leather. The arrangement of the upper deck is substantially the same as that of the double-deck Fifth avenue busses so familiar to New Yorkers, the deck being surrounded by a substantial pipe railing and a guard of netting; a curved stairway at the rear leads to the roof. Mahogany finish, with electric dome lights, makes the interior decidedly a pleasant place to ride in, and in warm weather the plate glass windows are dropped out of sight into pockets. The driver has a separate compartment of his own, which he enters from the right hand side of the car, so that in inclement weather he is thoroughly protected—an arrangement calculated to make the driver of a Fifth avenue bus turn green with envy.

The U. S. Grant Hotel will use its new "land liner" not only for conveying guests to and from the railroad stations, but will also run it on sight-seeing trips in the neighborhood, for which purpose it is well adapted.

HUGE BUS IN USE BY A CALIFORNIA HOTEL

Willys's "Baseball Day" in Toledo.

John N. Willys's annual "baseball day" in Toledo was even more of an affair than was the case last year, when it was inaugurated. The parade to the grounds to view the opening game between Toledo and Milwaukee was really in the nature of an industrial turnout, which emphasized the importance of the automobile industry, some 5,500 men and women being in line. They comprised the employees of not only the Willys-Overland factory, but the Kinsey and Warren companies, in both of which Willys is the dominating factor. President Willys and the other officials of the three companies headed the parade, which was made up of four divisions, each led by a band, all of the paraders displaying a cane bearing an Overland pennant, and a badge bearing Willys's picture. Along the line of march and throughout the joyous demonstration which marked the game, moving picture men snapped the scene, of which there were many that were worth snapping. The band and the crowd and the flag waving made a scene that in all probability long will be remembered.

PROFITABLENESS OF AUTOMOBILE BUSINESS DEBATED

North Dakota Implement Dealers Takes Sides and in Open Meeting Discuss the Subject—An Expression Given to Some Instructive Views and Figures—One of Them Argues Against Himself—Factors That Make for Success or the Lack of it.

When the man made up the program for the last annual meeting of the North Dakota Implement Dealers' Association, he created a somewhat unusual state of affairs. He thought it would be diverting and instructive to have discussed the profitableness of automobiles when sold in connection with agricultural implements. Accordingly he programmed such a debate, placing it in the form of a resolution as follows: "Resolved, That the handling of automobiles is not profitable for the average implement dealer." To the affirmative side he assigned C. O. Russell, of Devil's Lake, and to the negative F. W. McRoberts, of Casselton. It so happened that both men for several years have successfully handled automobiles in conection with implements, but apparently the program maker was unaware of the fact, at least so far as Russell was concerned. Russell, nevertheless, accepted the task, and after good naturedly explaining his apparently inconsistent position he proceeded to show how and why under certain conditions the sale of automobiles is unprofitable. His assertions and illustrations, taken in connection with his opponent's defense of the automobile business, threw some instructive sidelights on the subject which can be turned to advantage by not a few of those who are engaged in the trade, whether or not they are handling automobiles in connection with agricultural implements.

In his effort to prove that the profitable business in which he is engaged really is unprofitable, Russell said:

"Is it profitable for the ordinary implement dealer to handle automobiles? The only way I can see that this can be decided is to get down to actual figures. To do this we will suppose a case. Take the average implement dealer in a small town, say of seven hundred people. First, you must consider that there are always at least two dealers in a town of this size. This fact you must bear in mind all through the argument, and that is, the man we have in question gets only one-half of the business of that territory. For convenience sake, we will call this dealer Mr. Jones. We will start at the time when he has picked out his car and has made a contract, saying nothing about the time and money he has spent in looking up the different cars to see which is best suited to his particular needs. He has picked out a car listed at $1,000 and the contract calls for a dealer's commission of 15 per cent.

"Now, we are going to count our chickens before they are hatched, and Mr. Jones is going to sell four cars in the season. His commission on these four cars is $150 apiece, and will amount to $600. Mr. Jones has made $600. We will now see how he has spent this. In the first place, when he made the contract for the cars, he made a deposit of $50 per car, or $200. Of course, when his contract is up this money comes back to him, but he has lost the interest on it at 8 per cent., which amounts to $16. Then, about the first of February, someone comes in and makes the fact known that he is thinking of buying an automobile some time. Mr. Jones immediately gets busy and commences to talk automobiles. He probably puts in half a day, and then his prospect says that he will not buy an automobile under any consideration without first seeing the car. Mr. Jones feels certain that he can sell this man, so orders a demonstrator. In the course of a few days the car comes, with a bill of lading attached to it for $850, and we will say for the sake of easy figuring the freight on this car amounts to $50, making a further investment of $900.

"On the first day, Mr. Jones hunts up his prospect and takes him out for a little demonstration work. By this time he finds that his prospect has talked with other agents for automobiles and is not quite so sure that he wishes to buy now, as he will not be able to use it until the 15th of April, and at that time he will see about it.

"I merely mention such a situation to establish that foundation for the statement which I now make: That it will take four good days for any man to sell a car, and that this would be at least the average time it would take to close a deal. Some persons would take more, others less. Now, then, Mr. Jones's time, if he is running a successful business, it worth at least calculation $100 per month, or $4 per day, making the wage cost for selling each car $16, or $64 for the four cars which he sells. The unloading of these cars will cost him $2.50 apiece, or $10 for the four. Filling up each car with gasolene and oil, which the dealer will do for his customer on seeing that he has made a good profit on each car, will cost him $3 each, making $12. Further, Mr. Jones will find that when he comes to deliver the car his customer does not want the car that he has been demonstrating with, but will want a new car. Therefore, he will have to keep the demonstrator and get a new car for the customer, and he will find the same excuse when he comes to deliver the rest of them, so that at the wind-up of the season he will have worn out one set of tires.

"About that time he has had enough of the automobile business. He will have to buy a new set of tires, costing about $100, put them on his car, and then offer his demonstrator for sale at a discount, and he will be lucky if he sells it for a discount of $300.

"In one of his sales he ran across a customer who was what we call a tightwad, and in order to make this sale he discounted the car the amount of the freight, thereby losing $50 of his commission. Then, counting the time spent with prospects to whom the other fellow sold cars, he has spent fifteen days, which, at $4 per day, would amount to $60. Oil and gasolene that he used while demonstrating, $22.50. Then the repairs on his demonstrator—tire punctures and one broken spring—would amount to about $9.

"The interest on the money invested in his demonstrator for eight months amounted to $42. Figuring up the total of these amounts, we have $709.50. Subtract this amount from his commission of $600, and this would leave him a net loss of $109.50 for selling four cars.

"There are numberless other small items of expense that will be added to this loss, such, for instance, as when one of Mr. Jones' customers who lives out in the country telephones and says that he has tried for two hours and a half to start the car and it will not go, and he wants Jones to come out and start it for him. Mr. Jones goes out and finds that he has shut off the gasolene, his tank is dry, he has failed to turn on the switch, or his batteries are disconnected, or a hundred and one other reasons why the car did not start, and which any man could fix if he would use his head; but Jones has had the expense of going out there.

"I do not want you to gather the idea from the argument I have presented that there is not money in the automobile business; but the business of selling automobiles is a business by itself, and should be run as such, and cover all parts of the automobile field. I do claim that there is no money in the business of selling automobiles alone, for any man, no matter what kind of business he may be in; but that in order to make a success of the automobile business he must not only sell automobiles, but repair and store them and sell accessories for them, and have one or more of his own, so that when the weather and

Digitized by Google

roads are in good condition he will be able to add to his income by doing a livery business. The whole must be governed by more than the average amount of good judgment and strict attention to business. I believe that the average implement dealer, with the average amount of territory tributary to his place of business, can find an outlet for all the energy and ambition that he is capable of putting forth in taking care of his share of the implement business, bearing always in mind that anything worth doing at all is worth doing well."

In combatting Russell's contentions and in seeking to prove that the automobile business is worth while, McRoberts did not "paint the lily." He showed that it is possible to lose money as well as make it, as is the case in all businesses.

He remarked that when the average dealer who sells automobiles goes to figure up his profits during the first year in business, he had better carry a shock-absorber in his pocket, as he is very liable to receive a shock. The dealer contemplating going into the automobile business should be very careful in the selection of his car. He must get a car that would stand up to the work and behind which the dealer could stand with his guarantee, otherwise the business would be a disappointment from the start. He didn't believe in getting into the business in a town in competition with one or more other dealers in the same town. He believed a dealer who intended engaging in the automobile business should plan to get a territory of at least a county, in which to have a chance to do business. His suggestion was that the dealer do not wait until prospects came to him, but that he get busy in advance. At this time of the year he thought it a good plan to write personal letters. He believed in getting in touch with the man who had the price to pay for a car, and by carefully following the matter up and keeping in touch with the prospect, the dealer would find when the buying season rolled around that he had a number of prospects in view. Then, when he made a sale, he explained to the purchaser his manner of handling replacements, told him whether certain parts would be replaced without charge, and what parts would be charged for. Also he explained the manner of handling the car, what parts to oil, how to clean it and care for it, in order that the owner might keep the car in the best possible condition. Then, when he came back after new parts in case of accident, there was a distinct understanding as to what he must buy and what would be replaced free under certain circumstances.

He believed a dealer should have a large territory in the automobile business. He should have at least a county, and then, by creating sub-agents, he could sell a great many more cars than could be sold direct through his personal efforts. That there was scarcely a county in the United States that would not take from thirty to forty cars. Dealers would find the expense of selling thirty machines would be little more than the expense of selling four, as the organization already was made up, and a man engaged in the machine business must keep his organization in working order the year around. Then he said that there was no use in going into the automobile business if you were going to eat up all your profits giving to the sub-agents or the customer a lot of parts or accessories. He said it was unnecessary to throw in carburetters or other parts, or oil or gasolene; that the purchasers would get these items free if they could, but it was unnecessary for the dealer to give them. That the margin of profit in automobiles was small enough at the best, without reducing it through giving away extra parts and equipment. He said that the profit in the automobile business for the retail dealer lay in the volume of trade. That a dealer might do a business of from $5,000 to $10,000 a year at a loss, but if he made such arrangements in buying his cars that he could increase this business to $40,000 or $50.000 he might find some profit in it. Then, if he could increase it to $80,000 or $90,000, he would find it a very profitable department of his business, as $80,000 or $90,000 of business could be done at no greater overhead expense that a business of from $40,000 to $50,000. It was in the volume that the profit lay, and unless the volume could be provided, he did not recommend dealers to engage in the automobile line. He said that they should reduce the overhead expense to the lowest point, and then, if the volume could not be increased enough to show a profit, he might as well give it up.

He said further that he did not know much about the automobile livery business, but did not regard it as profitable. He also said that dealers were liable to do too much demonstrating; that a prospective purchaser could be convinced with one or two demonstrations as well as with a dozen, and every demonstration cost money, and he thought sometimes the prospect was scared away when the dealer appeared too anxious to make the sale. In his opinion, the main thing was to get a good machine, and sell for cash. He also warned the dealers to keep the demonstrators in good running order. He said he had known cases where a prospect was lost because they had to fuss with the demonstrator before they could get the machine started. He said that nothing impressed a new enthusiast more than a car which was started easily and quickly. In regard to cash sales, he said that if the sale was not made for cash then it should be settled for with a bankable note; that a man who neither had the money nor the credit with which to pay practically cash for an automobile had no business owning one, and the dealer was not showing judgment in selling him. He believed in all cases any dealer could make money selling automobiles.

McRoberts remarks roused Russell sufficiently for him to call attention to the fact that it was the "average dealer" whom he referred to. He added there was no county in the State that couldn't stand thirty cars, or perhaps 100, but that in his county (Ramsey) there were twenty-three average dealers, and if each secured the county agency and each sold thiry cars, that would mean 690 cars for Ramsey County, and no county in North Dakota could stand it. He was still of the opinion that the average dealer, under the present selling plan, did not stand much show of making money. He said that if a firm had the county agency then they were practically in the automobile business exclusively, and could not be rightfully regarded as a part of the implement trade.

Mr. McRoberts replied that last year the automobile business of his company amounted to $60,000, and their machinery business to $180,000, so he figured he was entitled to believe that he had done some machinery business as well as some automobile business. He said that the position of his company was that the horse vehicle trade had been so greatly reduced in volume by the introduction of the motor car that they must have something to take its place, and that is why they were engaged in the automobile business. So far as his people were concerned, they considered it a profitable department, and he believed the average, active, intelligent dealer could do as well with the business as they had done.

To Prevent Motors Slopping Oil.

Motors built with packing glands around the valve tappets or other provisions to limit the escape of the oil from the crank chamber through the valve guides are in the minority. Where such provision is not made a slight amount of wear on either the tappet or the tappet guide will allow more or less free passage for the escape of the lubricant, and the maintenance of a clean motor is an utter impossibility. The remedy is simple. Remove the tappet and mount it in the lathe and cut a slot about midway between the top and bottom. From this circumferential slot cut a longitudinal slot to the base of the tappet. The oil will collect in the slot around the tappet and be returned to the base.

How Ignition May Form Carbon.

Accumulations of carbon have been blamed on lubricating oil, on gasolene and on carburation, but there is a strong probability that inefficient ignition is responsible for a great deal of carbon for which some other cause is thought to be responsible. A half-burned charge will make a deposit of carbon, and poor ignition will result in half-burned charges.

Wrong and Right Ways to Wash Tires.

A mistake that not infrequently is made is the washing of tires with a mixture of kerosene and water employed for washing the body of a car. This, the Michelin tire man warns, is anything but right, for, as most everyone knows, oil is death to rubber.

Motorphobe Pays High for His Outburst.

The rural resident, who in many instances has an inherent hatred of automobiles, often makes himself exceedingly disagreeable toward motorists, and as a "road hog" and other types of animal, sometimes "gets away with it." The extent to which such motorphobes can carry their hatred recently was instanced in a court case, in which the man concerned paid a stiff price for a remarkable display of roadside temper. L. M. Carlyle, of Watertown, S. D., was the object of the judge's wrath. According to the testimony, Art Greer, a business man, was driving on a country road one dark night, when Carlyle turned his team across the road, threatened to horsewhip Greer, and further emphasized his feelings by drawing his knife and slashing one of Greer's tires, and then drove Greer from the car. In court, Carlyle pair $68.60 for his outburst. Carlyle's bitterness is said to have been the consequence of the frightening of a four-horse team he was driving by an automobile which he attempted to pass.

Shaky Tanks Make Leaky Joints.

A cause of leakage in the joints of the gasolene line that is of infrequent occurrence but sometimes is found where the tank is big and heavy and the piping stiff, is slight movement of the tank on rough roads, which causes the joints to "work" and gradually destroys their tightness. Gasolene will percolate through an extremely small aperture and it takes very little to start it dripping. It will pass quite readily through a crack that will not leak a drop of water.

1,005,123. Attachment for Tire Inflating Pumps. Henry K. Austin, Reading, Mass. Filed Nov. 12, 1909. Serial No. 527,742.

1. The combination with a rigid tube having a nipple at one end adapted to frictionally engage the bore of a rubber tube, the other end of said rigid tube being provided with a flattened annular flange forming a seat, of an elastic terminal coupling plug bearing upon said seat and provided with a bore to receive the nipple of a tire valve, and a telescopic casing of sheet metal formed of members independent of said tube and inclosing said plug, one of said members engaging said flange, said members having overlapping portions engaging each other at a point intermediate the ends of said plug, whereby the casing may be contracted to press said plug against said seat.

1,005,149. Automatic Valve for Pneumatic Tires. Henry W. Brink and William M. Brink, Indianapolis, Ind. Filed Jan. 17, 1911. Serial No. 603,161.

1. The combination with a vehicle wheel provided with a pneumatic tire, of a pneumatic tire inflating device comprising a wheel hub, said hub being provided with an air outlet passageway having its mouth located in the face of the shoulder on said hub, a shoulder formed on said hub, a collar surrounding said hub and abutting the shoulder, said collar having an annularly extending air receiving groove in the end adjacent to the shoulder, said groove registering with the air outlet passageway in the hub with the tire, and means to hold said collar stationary.

1,005,171. Running Gear for Motor Vehicles. David M. Dearing, Jackson, Mich. Filed Nov. 12, 1909. Serial No. 527,624.

1. In a motor vehicle running gear, the combination of a supporting frame, a front axle, an upper connecting member on the under side of the frame, a lower connecting member having its central portion housed within said upper connecting member and its ends arranged over the ends of the axle, a sleeve inserted through the central portions of said members, to pivotally connect the same, cushioning devices arranged between said members at opposite sides of said sleeve, and springs arranged between the ends of the lower connecting member and the axle.

1,005,186. Transmission Mechanism. Henry Ford, Detroit, Mich. Filed Aug. 12, 1909. Serial No. 512,502.

1. In an automobile, a motor having a flywheel and a shaft with an extension beyond the flywheel, a transmission shaft in substantial alignment with the motor shaft, a sleeve journaled on the extension in nonrotatable engagement with the transmission shaft, a brake drum rotatable on the extension secured to the sleeve, a clutch adapted to lock the drum and extension together, and a change speed and reverse drive planetary train adapted to drive the brake drum and sleeve from the flywheel and extension.

1,005,201. Pneumatic Cushion for Vehicles. Caleb Stevens Gurney, Portsmouth, N. H. Filed Nov. 21, 1910. Serial No. 593,565.

A device for the purpose set forth comprising a cylinder closed at both its ends and provided in one side with upper and lower vertical series of lateral openings extending only part way to the ends of the cylinder, a piston slidably mounted in said cylinder, and valve plates secured to the upper and lower sides of the piston and fitting closely against the inner surface of the cylinder to alternately cover and uncover the lateral openings in the cylinder when the piston is reciprocated.

1,005,284. Spring Suspension for Motor Vehicles. Emil A. Nelson, Detroit, Mich. Filed Dec. 26, 1908. Serial No. 469,316.

1. In a spring support for vehicles, the combination of a semi-elliptic spring supported with its ends free to move outwardly, and springs for assisting the outward movement of the ends of said spring exerting a constant force upon said ends, in the direction of the length of said spring.

1,005,291. Friction Driving Mechanism for Motor Vehicles. Edwin G. Owen, Wysox, Pa. Filed Apr. 29, 1911. Serial No. 624,074.

1. A friction driving mechanism, comprising a drive wheel, a rocker having tubular arms, rods extending at one of their ends into said arms, springs secured to the inner ends of the arms, friction rollers carried by the outer ends of the arms and adapted to engage the periphery of the drive wheel, a drive shaft, and a gearing between the drive shaft and the rollers.

1,005,300. Carburetter. Burt Neulon Pierce, Indianapolis, Ind. Filed Jan. 3, 1910. Serial No. 536,200.

1. A carburetter including a mixing chamber with a main air inlet at one end and a gas outlet at the other end, a spring held wing valve in and extending transversely of said mixing chamber with the lower part thereof cut away to form a normal passageway thereunder for a current of air from the main air inlet, a fuel inlet entering the mixing chamber at the bottom thereof immediately behind the said wing valve, and a secondary air inlet in the bottom of said mixing chamber that is located immediately behind said fuel inlet.

1,005,306. Combined Signal and Sign-Displaying Lamp for Vehicles. Almor Manor Puckett, San Antonio, Tex. Filed Dec. 1, 1910. Serial No. 595,146.

1. In a device of the character described, a frame for holding and displaying individual interchangeable letter or number plates, comprising ends, top and bottom having parallel inwardly projecting flanges at their opposite front and rear edges forming longitudinal slideways for the plates the top being provided with an opening at one end to admit one plate at a time into the slideway, means for closing the opening, means for securing the closing means in place over the opening, and strips connecting the outside flanges of the top and bottom in position to cover the meeting edges of the plates.

1,005,326. Cushion Tire. Phillip Schau, Kalamazoo, Mich. Filed June 22, 1910. Serial No. 568,357.

A tire comprising a separable outer casing; a cushion member consisting of a band corresponding to the tread, conformed to said casing and having inwardly projecting cones thereon, the outer sides of the outer cones being conformed to the said casing; and an inner member corresponding to the rim having its edges conformed to the said outer casing and provided with annular grooves disposed to seat the inner free points of said cones.

1,005,332. Automobile Spring Tire. Niram A. Schneider, Mitchell, S. D. Filed Nov. 29, 1910. Serial No. 594,736.

1. A tire comprising a channel plate, bolts for securing said channel plate to a wheel rim, the head of each of said bolts provided with a central threaded socket and with a side socket, a resilient washer, a screw passing through said washer and within said threaded opening to hold said washer upon said bolt, a spring surrounding said head and having its end fitted within said side opening, a relatively larger spring surrounding said first mentioned spring, and secured to said channel plate, the tread portion resting upon said larger springs, and a casing surrounding said tread portion and adapted to be secured between said channel plate and the rim of a wheel.

1,005,362. Speed Regulator for Gas Engines. Albert H. Thomas, Springfield, O., assignor of one-third to Grant M. Smith and one-third to Charles W. Foster, Springfield, Ohio. Filed May 29, 1905. Serial No. 262,787.

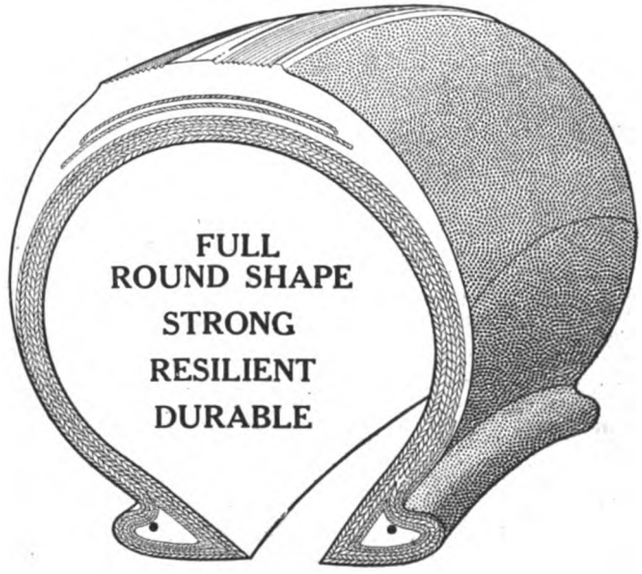
1. A mechanism controlling the speed of an engine, comprising in combination with the flywheel, driving shaft and a sliding valve-operating rod, a bevel-ended spool splined to the driving shaft, a lever pivoted adjacent said driving shaft and adapted to engage at one end a lug on said rod and at the other end provided with a roller adapted to engage the beveled end of said spool, and a governor mechanism adapted upon the speeding up of the engine to throw said spool so as to permit the end of said lever to engage said lug on said rod.

1,005,386. Air Purifying Device for Internal Combustion Engines. Herman E. Whiting, Palmyra, N. Y., assignor to Garlock Auto Specialty Company, Palmyra, N. Y., a Corporation of New York. Filed May 4, 1910. Serial No. 559,293.

1. An air purifying device comprising a liquid receptacle having an outlet conduit, and a filtering element removably supported by said liquid receptacle and having an unrestricted discharge conduit extending therethrough and connecting with the conduit of the liquid receptacle above the liquid level of the latter.

1,005,449. Cushioning Device for Vehicles. Michael G. McGuire, Chicago, Ill. Filed Aug. 9, 1910, Serial No. 576,287. Renewed Aug. 10, 1911. Serial No. 643,402.

1. A cushioning device for vehicles comprising a pneumatic cushioning element surrounding and secured to the axle of the vehicle and with the air in contact with the axle, shoes secured to the upper and lower faces of said element, flexible connections on opposite sides of the element connecting said shoes, and means connecting one of the shoes with the springs of the vehicle.



1,005,457. Internal Combustion Engine. Friedrich Oberhansli, Bregenz, Austria-Hungary. Filed Nov. 28, 1910. Serial No. 594,558.

1. In an internal combustion engine of the compressed air ignition type, the combination with the power cylinder of a combustion chamber at the end thereof, an atomizer nozzle arranged to open into the combustion chamber, a cut-off valve in the atomizer nozzle, a spring for normally holding the cut-off valve in closed position, a pump for forcing the liquid fuel through the atomizer nozzle past the cut-off valve, an overflow valve, an operating lever for the pump actuated from the engine shaft, a stud, an eccentric adjustably mounted on

MICHELIN TIRE COMPANY
Milltown New Jersey

Digitized by Google

the stud, a regulating lever mounted on the eccentric and adapted to control the overflow valve, and a link connecting the regulating lever with the operating lever whereby the pump and the overflow valve are operated according to the speed of the engine substantially as described.

1,005,470. Tire. Charles L. Rempes, Akron, Ohio. Filed Aug. 16, 1910. Serial No. 577,468.

1. In a tire, the combination with an outer casing provided with annular ears and having inclined edges, of an integrally formed rib extending inward from the casing and having a flaring end adapted to be engaged between the inclined edges of the casing.

1,005,473. Elastic Wheel Bearing. Gustaf Rennerfelt, Scranton, Pa. Filed Feb. 4, 1907. Serial No. 355,592.

1. In a bearing, a pressure transmitting member, a track, a plurality of flexible hollow rollers, and another flexible roller within each of said flexible hollow rollers.

1,005,479. Lifting Jack. Herrman A. Schatz, Chappaqua, N. Y., assignor to Acme Ball Bearing Company, Chappaqua, N. Y., a Corporation of New York. Filed Jan. 17, 1908. Serial No. 411,315.

1. In a lifting jack, the combination with a standard, of a vertically disposed lifting screw, a worm wheel rigidly secured thereto, a lifting cylinder operated by said guard consisting in part of a rim attachable to said hand-piece, and absorbent material securing means in that portion of said guard that covers the working portion of said tool.

1,005,484. Carriage Fitting. Albert W. Smith, Providence, R. I., assignor, by mesne assignments, to The Columbia Motor Car Company, Hartford, Conn., a Corporation of Connecticut. Filed Dec. 2, 1907. Serial No. 404,871.

1. In combination, a plurality of bows or ribs for carriages, of spacers, interconnecting means for flexibly holding said spacers and for clamping them together with said bows.

1,005,491. Carburetter. Alfred Weiland, Philadelphia, Pa. Filed Jan. 21, 1909. Serial No. 473,406.

1. In a device of the character described, a main reservoir, a mixing chamber adjacent thereto, a fluid inlet to said reservoir, a mixture outlet from said mixing chamber, a throttle valve, an auxiliary reservoir having communication with said main reservoir, and said mixing chamber, a main air valve, means to supply a mixture of air and fluid to said mixture outlet when said main air valve is closed and means to simultaneously control said throttle valve and said air valve.

1,005,507. Starting and Reversing Mechanism for Multicylinder Internal Combustion Engines. Hans Theodor Bruns, Nuremburg, Germany. Filed Dec. 23, 1909. Serial No. 534,590.

1. Starting and reversing mechanism for multi-cylinder internal combustion engines, comprising a compressed air vessel, two distributing valves, operating members, a reversing member adapted to alternately actuate said operating members to operate either of the said distributing valves, a starting valve, conduits connecting the said distributing valves with the said starting valve and cams adapted to engage with said distributing valves respectively.

1,005,528. Automobile Jack. Joel B. Foster, Shelbina, Mo. Filed Jan. 31, 1911. Serial No. 605,837.

1. An automobile jack provided with supports for the power end of an automobile for sustaining the power end of the automobile in an elevated position, skids for the power wheels having the ends remote from those first receiving the wheels of the automobile adjacent the automobile supports and movable sustaining means for the second named ends of the skids responsive to the power wheels of the automobile for movement of the skids out of operative relation to the said wheels.

1,005,541. Engine Starting Apparatus. Edward A. Halbleib, Rochester, N. Y., assignor to Northeast Electric Company, Rochester, N. Y., a Corporation. Filed Dec. 16, 1910. Serial No. 597,732.

1. An engine starting device having, in combination, a manually operable member movable both longitudinally and rotatively, an air pump operated by the longitudinal movement of said member, a fuel-controlling device operated by the rotative movement of said member, and a mixing chamber into which the air pump and the fuel-controlling device discharge.

1,005,570. Governor. Lewis Riley O'Neill, Montclair, N. J. Filed Sept. 6, 1910. Serial No. 580,583.

1. In an explosion engine provided with a wheel having a hub thereon, a sleeve or collar on the hub and provided with a circumferential beveled face directed toward the wheel, transmitting mechanism connected to the beveled sleeve or collar and holding the same against rotation, a spring in engagement with the sleeve or collar at the end thereof remote from the beveled face, centrifugal members mounted on the wheel of the engine, and a beveled shoe on each centrifugal member having its beveled portion in operative relation to the beveled face of the sleeve or collar.

1,005,581. Valve. Alfred C. Stewart, Los Angeles, Cal. Filed Nov. 22, 1909. Serial No. 529,476.

In a valve, a sleeve having internal threads at its lower end adapted to be screwed onto a threaded valve stem, the upper end of said sleeve having a reduced threaded end for the attachment of an inflating tube and having an intermediate threaded portion, said sleeve being provided with an internal shoulder near its upper end and with an internal shoulder near its lower end, a thimble seated against the lower internal shoulder and forming a lower valve seat, the upper shoulder forming an upper valve in said first shell, a lift secured to said second shell having a recess in its upper face, an inflated rubber body inclosed by said two shells tending to move the same in opposite directions, and projections on said rubber body seated in said recesses.

1,005,589. Cushion Tire. Milton J. Altland, Dillsburg, Pa. Charles Altland administrator of said Milton J. Altland, deceased. Filed Mar. 12, 1910. Serial No. 548,840.

1. In a vehicle wheel, comprising a rim, an outwardly extending central portion secured to the rim, springs extending around said central portion and having laterally turned ends resting in a depressed portion of the rim to bring the outer face of the ends flush with the outer face of the rim, a covering for said springs and having laterally turned ends resting upon the outer face of the ends of the spring and rim, and means for securing the laterally turned ends of the covering on the rim.

1,005,690. Automobile Tire Pump. Frank E. Carlson, Chicago, Ill. Filed Oct. 24, 1910. Serial No. 588,711.

1. A tire pump comprising an air cylinder having an intake opening in its central portion, spaced pistons operating in said cylinder at each side of said opening, a ring surrounding said cylinder over said opening, said ring being grooved on its inner side and provided with an intake opening leading to said groove, and a wire gauze covering for the opening in said ring, substantially as described.

1,005,701. Internal Combustion Engine. Theodore E. Friend, Norwalk, Ohio. Filed Sept. 24, 1909. Serial No. 519,362.

1. In a four-cycle internal combustion engine, the combination of a cylinder, a piston reciprocable therein, a crank-shaft, a rod connecting piston with the crank, a case inclosing each crank and adjacent end of piston rod and communicating with the cylinder, thus forming a gas-tight chamber in which the piston rod and crank operate, a by-pass pipe communicating with such chamber and having a main inlet valve at one end and an outlet valve at the end adjacent to the top of the cylinder, means for operating such valves at the required times, as specified, an inlet valve and an exhaust valve arranged at the head of each cylinder, and means for operating such valves in the cycle or order of succession stated, whereby as the piston descends or makes its suction stroke, a charge is forced or transferred from the crank chamber into the upper or working chamber of the cylinder and whereby as the piston makes the first part of its return or compression stroke, a portion of the admitted charge is forced back out of the cylinder into the crank-case chamber, the inlet valve of the cylinder being closed during the latter portion of the compression stroke so that a complete charge is retained and compressed in the cylinder, a fresh supply of gas being admitted to the by-pass and crank case during such latter part of the compression stroke as shown and described.

1,005,707. Elestic Wheel for Motor Vehicles. William P. Hoopes, Milton, Pa. Filed Nov. 23, 1910. Serial No. 593,880.

In a pneumatic wheel of the character described, a bearing sleeve having an annular flange, a ring mounted slidably and non-rotatably upon the sleeve and co-operating with the flange to form a seat, said flange and ring having shouldered portions with faces disposed in parallel relation, a pneumatic tire occupying the seat and including a casing having flanges clamped between the opposed faces of the flange of the bearing sleeve and the ring slidable upon the latter, said tire being provided at intervals with outwardly extending lugs, a spoke ring supported upon the tire and provided at intervals with flanges between which the lugs of the tire are accommodated, a back plate, and a cap connected with the spoke ring and slidably engaging the seat flange and ring, and a cover plate secured upon the bearing sleeve and slidably engaging the back plate substantially in the manner and for the purpose set forth.

The Measure of Success is Results

It is deeds, not idle words, that count.

The DISCO Self Starter made 1912 a self starter year. It was the sensation of all the automobile shows.

The DISCO Self Starter was the first ever adopted as standard equipment by any automobile manufacturer—today 36 leading makers of cars at all prices use it—recommend it—bank on it.

The DISCO Self Starter has already made 30,000 motorists happy. This is about ten times the number of any similar device in use—more than all other self starters combined.

The DISCO is the only Self Starter using our patented "Starter" Spark Plugs, enabling us to equip Fords, Buicks, and other cars not having pet-cocks as easily as any others.

"DISCO"
(REG. U.S. PAT. OFFICE.)

The DISCO Self Starter is the first and only starter to be nationally advertised. Dealers know that it pays to sell an established commercial success. DISCO is the dealers best bet.

The DISCO Self Starter is distributed through 15 branches—we want dealers everywhere—can be obtained by **any** manufacturer or **any** dealer as fast as mails and express can operate. We have always made prompt shipments.

The DISCO Self Starter can be put on ANY car in a couple of hours—it has but 12 parts; weighs but 4 pounds.

The DISCO Self Starter naturally costs more than a cheap imitation. Progressive automobile manufacturers and dealers, however, realize that it pays to furnish the best, and that is why you find the DISCO on eight of the **highest-priced** cars built in America, as well as on cars at all other prices, down to the popular-priced models.

The DISCO Lighter — A New Twin

The DISCO Lighter lights gas headlights, turns them down, or turns them out, all from the seat. Simply press a button after turning on the gas and your lights are lighted. Complete with special coil, special burners, all wiring and tubing, and complete instructions ready to install, $15.

Like the DISCO Starter, it is perfectly simple and simply perfect. Write today for wholesale prices and terms.

Wants and For Sale

15 cents per line of seven words, cash with order. In capitals, 25 cents per line.

CAN YOU SELL CARBURETERS? There is a wonderful opening for a high-grade, competent salesman who is not restricted in his ability to do big things. We have the finest commercial carbureter proposition on the market and are looking for a man who can take it to the biggest manufacturers in the industry and sell it. There is plenty of opportunity not only for salary but for an interest in the business to the man who makes good. No cash capital required—simply brains and a highly developed ability to sell. Address, CARBURETION, care of Motor World.

WANTED—Superintendent; man with thorough knowledge of the manufacture of leather tire treads and all factory costs connected therewith. Address SUPERINTENDENT, Motor World.

AUTO CAR runabout, 2 cylinder, 12 horsepower, new tires, excellent condition; extra shoes and tubes. WM. WELLING, Somerville, N. J.

EXTRA FINE BLACK JAPAN—For enameling automobile lamps, radiators, fenders, etc. Will not crack, chip or peel. One coat covers solid. Air drying or baking. Have your dealer order today. THE COLUMBUS VARNISH CO., Columbus, Ohio.

DEALERS—Get agency proposition for Cutting Cars. Write for information to CUTTING MOTOR SALES CO. OF CANADA, 76 Adelaide St., West, Toronto, Canada.

FOR SALE—Garage and Auto Livery business, two five-passenger cars, tools and supplies. Will sell one or both cars. This is a bargain. Best location in the famous Judith Basin. MARTIN AUTO CO., Hobson, Mont.

SPLENDID White Steamer, only $225.00, perfect order, five good tires and extras. Runs beautifully. Exchange for Model T Ford Roadster. Demonstration given and required. Write if you mean business. TRIPPE, Toms River, N. J.

WANTED—Gasolene Pump! Self-measuring, little used, must be A1 condition. Address LOCK BOX 66, West Acton, Mass.

FOR SALE—1911 Hupmobile runabout, in excellent condition. P. W. WOOD LUMBER CO., Worcester, Mass.

FOR SALE—Patterns, drawings and parts for 4 x 4 water-cooled, opposed motor; just the equipment for light delivery wagon. H. A. SPILLER, 83 Kenwood St., Dorchester Center, Mass.

FOR SALE—16 H. P. Jager gasolene engine, 2 cylinder, type R. Only one month's continuous use and recently overhauled. HOLBROOK, CABOT & ROLLINS CORPN., Navy Yard, New York.

PARCEL DELIVERY WAGON—Cadillac light delivery, late model, ready to give a year's service without spending any money; equipped with good tires; sacrifice at $325. BARNET, 509 7th Ave., New York City.

NO REGARDS FOR DISTANCE—If you are east of the Rocky Mountains—we will allow all freight on a barrel of genuine Packard auto oil at 29c. no charge for barrel, which empty and sold will reduce your oil cost to about 27c. Send us your order for a bbl. and save money. ALBERT E. HALE CO., 3 P. O. Sq., Springfield, Mass.

DELIVERY, 2,000 lb. Express Type—Rapid one-ton truck with express body, shed and tailboard, guaranteed, overhauled; practically new tires; ready to go to work with; will sell, account death, at $550. MRS. SIMPSON'S CAR, 511 7th Ave., New York City.

MAILING LISTS of automobile owners in Atlanta and several States. 303 Kiser Bldg., Atlanta, Ga.

BARGAINS in new 4 x 5 4-cylinder auto motors. Equipped. F. E. ALFORD, Goshen, Ind.

FOR SALE—Half interest in an Automobile Garage and Repair Shop in one of the best towns of the Southwest. Best business in the city. A safe investment. Reason for selling—must get out in the open. For further particulars, BOX 202, care Motor World.

FOR SALE—Model F Stanley steamer, cheap, $300. H. P. BEEBE, Fredonia, N. Y.

MAILING LISTS of Automobile Owners. S. H. CARROLL, JR., Albany, N. Y.

A TREMENDOUS SACRIFICE—A professional lady leaving city, indefinite period, will sacrifice Ranier 5-passenger 4-cylinder 30-H. P. touring car; top, folding windshield, high tension magneto, extra shoes, tubes, tools, etc.; $300; warranted perfect running order. MRS. STOUTENBERGER'S CAR, 1075 Intervale Ave., Bronx, two blocks from subway, New York City.

GASOLENE Rumble Seat Runabout; would make exceptionally fine truck; $100; also Cadillac Delivery Car, $100, running order. BINGHAM'S CHAUFFEUR, 1075 Intervale Ave., Bronx, near subway station, New York City.

WANTED—Ardsley touring car; state price and condition. C. H. CURTISS, Naugatuck, Conn.

AGENTS WANTED — To handle the $1000 G. J. G. "Junior," racy, classy and specially designed chaseabout with 104-inch wheelbase, with a real 26 H. P. motor, Bosch magneto, Dorian remountable rims with 32 x 3½ tires, at a price of $1,000, which is a money-maker for the sales agent. Write for literature and discounts to G. J. G. MOTOR CAR COMPANY, White Plains, N. Y.

QUALITY RUBBER CEMENT—Best in the World—Hotter the weather the better it sticks. For repairing automobile, motorcycle and bicycle inner tubes and tires. This cement is unequalled. Send 20c. in stamps for two sample tubes. For terms and discounts, write HENRY E. EBY, Fernwood, Del. Co., Pa.

AUTOMOBILE SPECIALTIES—Models and experimental work, electrical and mechanical, special auto parts, bearings, etc. AUGUST HORMEL, 587 Hudson St., New York City. Tel. 2873 Chelsea.

BARGAIN—$750 will buy a nearly new Mitchell 5-passenger automobile. New tires, Bailey tread, top, windshield and all accessories complete. Cost $1,500. As good as new, owing to short length of service. THE TRIUMPH ELECTRIC CO., Cincinnati, O.

GARAGE FOR RENT—Most prominent corner in Bergen section of Jersey City; entrance on two streets; floor space about 170 x 50 on ground floor, 100 x 50 on second floor; brick building with elevator. Apply to owner, T. W. LEAKE, Bergen Ave. and Montgomery St., Jersey City.

BROKEN CRANKSHAFTS, cylinders, crankcases, flywheels, gear teeth, pistons, perfectly welded and machined ready to replace. Guaranteed and references. Machinery up to 5 tons welded. ATLAS WELDING WORKS, 74-76-78 Irving St., Rahway, N. J.

BROKEN CYLINDERS, crankcases, etc., made good as new by welding at about ¼ cost of new parts. No charge unless weld is satisfactory. Write for references and complete information. WATERBURY WELDING CO., Waterbury, Conn.

EXPERT CHAUFFEUR, motor boat operator and repair man wants work at once. Sober and reliable. Seven years' experience. Address, BENJ. SPRAGUE, 55 High St., Claremont, N. H.

ELMORE TOURING CAR, 1911, fully equipped, extra tires, warranted fine condition, like new, great roadster, price $750, act quick, send for full description. H. J. DANIELS, Norwich, N. Y.

SCORED CYLINDERS repaired, $12 each. No enlargement of bore—no need for new pistons and rings. Send piston with cylinder. Absolutely reliable method. Better investigate and save money. References, testimonials, and full details on request. WATERBURY WELDING CO., Waterbury, Conn.

SALESMEN, one who is now visiting automobile trade or owners. Good money made on a very attractive proposition. STURDY MFG. CO., 2637 Michigan Ave., Chicago, Ill.

LOCOMOBILE—Forty horsepower. Special bargain for anyone wanting a first-class high grade automobile. In first-class condition. Full equipment including fore door torpedo body, nickel trimmings, top, Warner Odometer, Prest-O-Lite, Klaxon, shock absorbers,, seat covers, Kellogg air pump, tire trunk, Rushmore headlights, combination electric and oil lamps. 100 Wright St., Newark, N. J.

NEUSTADT'S 1912 200-page Automobile and Motor Boat Accessory Catalogue, free for the asking. NEUSTADT AUTOMOBILE & SUPPLY CO., 3200-2-4 Locust St., St. Louis, Mo.

"HAYES" Metal Boxes

for Every Man Who Motors & for Any Make of Car

Your car needs a "Hayes" metal box for three reasons: for looks, for convenience, for safety. Maybe a big box, maybe a small one—but **every** car needs a "Hayes," and more than 250,000 cars already are using them.

"Hayes" boxes are low in cost, come in 15 standard sizes and a wide range of styles, and are of superior finish and extraordinary durability.

Style B—$5.00

With a "Hayes" on your running board, your tools, supplies, batteries, auto-conveniences of every sort are accessible at a moment's notice—**but only to the man with the key.** "Hayes" boxes for cars are made just like "Hayes" boxes for safety deposit—of rolled steel, electrically welded, fitted with "Hayes" special locks (that serve as cover-lifts). **Absolutely burglarproof.**

Of beautiful finish (enamel baked on), they do not chip, but hold their gloss indefinitely. "Hayes" boxes come in any color, fit any running board, are made with or without compartments and trays, and combine every feature desirable in a box for wear and looks.

There is a size and style that just suits your car, no matter what the make—and the cost is extremely low—from $3 to $12.

Carried by all accessory dealers.

FOR GARAGES—the "Hayes" drip pan is a fine convenience. It keeps the floor clean, and keeps tires out of the grease (grease is a mighty bad thing for rubber). Price only $2.

Write today for the "Hayes" catalog of Boxes. And when you buy your box, look for the "Hayes" trade-mark inside the cover.

Combination—$12.00

Why not change places with your customers on this tire question?

It might be a good thing for tire dealers to get on the other side of the counter once in a while and look at things from the viewpoint of the customer.

If you were buying tires instead of selling, what tires would you buy?

The ones that offered you the greatest tire value for the money, wouldn't you? And you undoubtedly would let the number of strong points incorporated in the tire determine its value.

When you found a tire that "stood up"—gave you a service return for every penny of your investment—you probably would tell your neighbor that your dealer sold Good tires. And your dealer would get another customer and his business would grow accordingly.

Why not sell the kind of tires you would buy if you were a customer—

UNITED STATES TIRES

They are the product of a four-fold system of manufacture.

They combine the strong points of Four world-famous brands of tires.

They are the Strongest Tires in the World. Why not handle them?

UNITED STATES TIRE COMPANY, New York

Dealers Everywhere. No Goods at Retail.

Are you interested in Motorcycles or Bicycles, either from your present business connections, or from the memory of "days gone by"?

In either case you should have the 1912 Spring Number of

THE BICYCLING WORLD FOUNDED 1877 and MOTOCYCLE REVIEW

It's a complete Handbook of the cycling business and contains an immense amount of valuable information showing the progress of the industry and its condition today.

Among its leading features are the following:

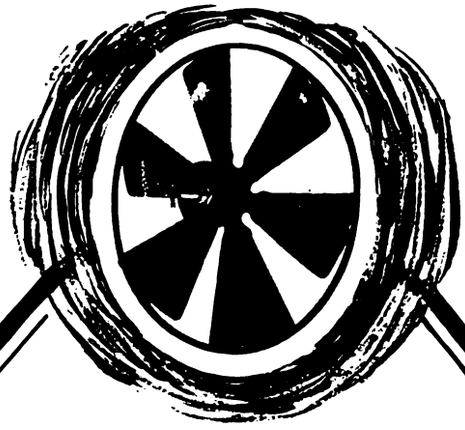
(1) A picture and description of all distinctive 1912 models of motorcycles and bicycles produced by American manufacturers. Each halftone is large enough to show the main points of the machine, and the description gives the distinctive features, equipment, etc., entirely without bias or selling argument.

(2) A halftone of the president and sales manager of each American concern making motorcycles or bicycles, published with the idea of showing the "man behind" the machine, and the man with whom the dealer does business.

(3) Cycling track records—both motorcycle and bicycle—up to date of going to press, arranged in form convenient for quick reference.

(4) A brief statement of the condition and plans of all of the really live clubs—several hundred of them.

The Spring Number will be ready for mailing April 27th. Send your order at once—the supply won't last long.



The price is 25 cents—BUT you need the cycling news every week, don't you? Then make your remittance $2.00 and you get the Spring Number and the next 51 issues.

Your tire maker is very anxious to impress upon you the importance of

Tires Inflated to the Right Pressure

He insists that this is tire economy and

Saves You Money

How do you know what pressure you have in your tires? A

SCHRADER
UNIVERSAL
Tire Pressure Gauge

(Trade Mark Registered in U. S. Patent Office)

(Patented March, 1898—Other Patents Pending)

will tell the exact pressure in your tires at any time, day or night, by simply holding this Gauge to your Valve for a second. Its recording sleeve remains in place, showing the exact pressure in the tire so that the Gauge can be taken anywhere and read, at night to the front of the car into the light of the lamps. After the pressure has been ascertained the Indicating Sleeve can be pushed back into the Gauge with your finger. No catches or snaps to operate or get out of order. This Gauge is 2½ inches long over all, short enough to apply easily to the smallest diameter of wheel and can easily be carried in the vest pocket or the change pocket of your trousers.

Price $1.00 Each

AJAX
TIRES
(Guaranteed 5000 Miles)

Strong Selling Talks for Ajax Dealers

In every Glidden Tour they have entered, Ajax Tires have always made the best showing. In the 1911 Glidden Tour all four of the trophy-winning cars had Ajax equipment, and not one of the sixteen casings had to be replaced during the whole rough trip of 1,454 miles.

Tires that make record trips like this and finish almost as good as new are the kind of tires dealers find profitable to handle. Ajax dealers report that tire business is always good with them.

Write for Ajax Inducements to Dealers.

Announcement

TWITCHELL AIR GAUGE

The Twitchell Gauge Co. have succeeded the Twitchell-Garvey Mfg. Co. and will in the future market the Twitchell Tire Pressure Gauges.

All patents, rights, etc., including the Twitchell trade name, have been taken over by this firm. Our rights and yours will be vigorously protected under Twitchell patent No. 927,298, which has been repeatedly adjudicated as valid by the courts.

The fine quality of workmanship and accuracy which has distinguished the Twitchell Gauges in the past will be maintained in the future, and this Gauge with the new stop feature, which has been perfected by Mr. Twitchell, is now ready for the market and will thus continue to be the leading Tire Pressure Gauge, as it has been since it first was put on the market.

Mr. Fred G. Bremer has succeeded Mr. James Garvey as manager of this firm.

Argo Style Means Efficiency

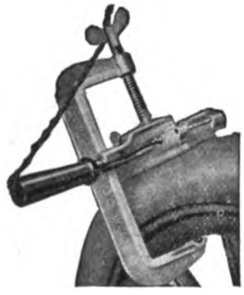
There is good good mechanical reason for almost every striking feature of the ARGO Brougham.

The long wheel base, low swung body and large wheels may at first seem only intended to add grace and beauty of line. They do that—and more.

The silent chainless enclosed power plant appeals first to the demand for a dignified noiseless pleasure car, but our engineers designed it also for long life—for economy of power—for efficiency.

Underneath the solid comfort and elegant luxury of the ARGO is a foundation of sound scientific principles. We shall be glad to tell you more of the ARGO policy if you will but say so. Write for our booklet.

ARGO ELECTRIC VEHICLE CO.



1201 S. Jefferson Avenue SAGINAW, MICH.

AGENTS AND DEALERS—The Argo Electric Wagon is another good business proposition. Ask us about both.

Before a customer kicks about tire trouble

tell him how a reliable vulcanizer will help him avoid it. Show him that sealing stone-cuts and sand-pockets with welds of new rubber will make tires give double or treble their usual service. Prove to him that he or his chauffuer can vulcanize tubes and casings at home. Then sell him a

SHALER Vulcanizer

Most motorists know the Shaler by reputation and will buy their vulcanizers from the local dealer who is ready to supply them. Other motorists will buy as soon as they see how well their neighbors are satisfied.

Models for every requirement—heated by electricity, steam, or by direct radiation—have the exclusive Shaler feature, a thermostat to control the heat automatically. Can not injure a tire.

Write today for dealers' proposition.

Who and what does

M & P ELECTRIC VEHICLES · DETROIT ·

stand for?

Briefly it stands for highly specialized knowledge in Truck design, construction and services. It stands for a union of extensive experience in the Building and Selling of both gasoline and electric cars. It stands for a "make good" Truck.

M stands for M. C. **Merriman,** Treasurer and Sales Manager. Has had long experience as automobile Dealer and salesman of gasoline and electric cars for pleasure and commercial use. In direct contact with the Trade, he made a special study of the commercial car situation. The result of this is shown in the simplicity, accessibility, high quality and moderate price of the "M & P" Electric.

P stands for Chas. **Pepper,** President and General Manager of the M & P Electric Vehicle Company. For past four years was Superintendent of the Truck Division of the Packard Motor Car Company, Detroit. For six years was General Manager for the Waverley Electric Company, builders of electric vehicles. Has been identified with the Automobile industry since its inception. A man of ripe practical experience. A man with first hand mechanical knowledge of every detail essential for the building of a high class practical product.

These two men backed by ample capital, in a plant with modern facilities are building

The M & P 1000 Lb. Electric Truck

K · D

The Motor With the Sliding Crescent Valve

KNIGHT-DAVIDSON

1896 — 1912

The CRESCENT valve of the K-D Motor, fitting around the stationary piston wall affords a larger port area than any other poppet or slide valve on the market. It is simpler and, consequently, better than any other valve construction known and is here offered to discriminating manufacturers, not as an experiment, but as a tried, tested and proved mechanical advance. The K-D motor is simple, silent, cools rapidly, has the simplest oiling system known, will not carbonize. Last and most important, will give on a given quantity of fuel more power, speed and endurance, unit for unit, than any other engine on any type of an automobile. We want to present some facts to interested manufacturers.

B & L CASTER FRONT AXLE

Makes a Big Winner in Philadelphia

Our Philadelphia Agent writes it is a Great Success.

A. S. BURNELL, President and General Manager,
1346 Michigan Avenue, Chicago, Ill.

Philadelphia, Pa., February 28, 1912.

Dear Sirs:—The axle is a great success, is running fine. Have made several demonstrations and every one says it's the only front axle that ought to be allowed to go on the automobile, for safety, easy steering and perfect control. Will sell the majority of those I have demonstrated for. Enclosed you will find order for one axle to go on a Studebaker car, 1908 model, more orders will follow later. Send us a big cut for we are going to run a one-half page in our newspaper, we will advertise it right. We will equip at least one thousand cars this year. Our new garage will be at 1907 after March 12th, N. 23rd St. Circulars received all O. K., thanks for same. Rush the order for axle, as every one on a car will sell several more. Yours very truly,

H. SCHROEDER,
President and General Manager Lake Schroeder Auto Exchange.

Philadelphia, Pa., 1418 Blavis St.

AGENTS WANTED for all cities in the United States to put the B & L Caster Front Axle on old cars. Exclusive territory given to good men. Our axle when on a car proves that it is the only safe axle made. In buying a new car demand that it be equipped with the B & L Caster Axle. Write for Agency Proposition. Address:

A. S. BURNELL, Manager Chicago Branch, 1346 Michigan Avenue.

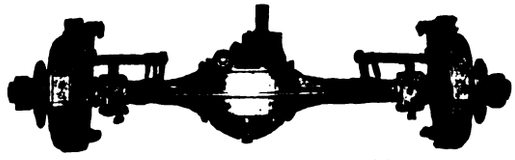
If You Need Motor Lamps
You Need This Catalog



We want you to write for the Solar Catalog before you decide on your motor lamps, for this is the most complete line of lamps on the market. Solar Lamps have been preferred by most motorists for the past fourteen years because of their brilliancy, their style, their strength and their several exclusive advantages - their special short focus lead glass lens mirror reflectors—the patented double ray light projection (in the Solarclipse), giving two distinct fields of light, for city and country use—the new black finish, the only such finish that's proof against heat and moisture—and other features that other lamps lack.

To fail to see Solars before you buy is to fail to include in your consideration the very finest lamps in existence. Solars are made for oil, electricity, gas and in combination, for pleasure cars, motor trucks, carriages, motor boats and airships. Write for catalog now—while you think of it. (136)

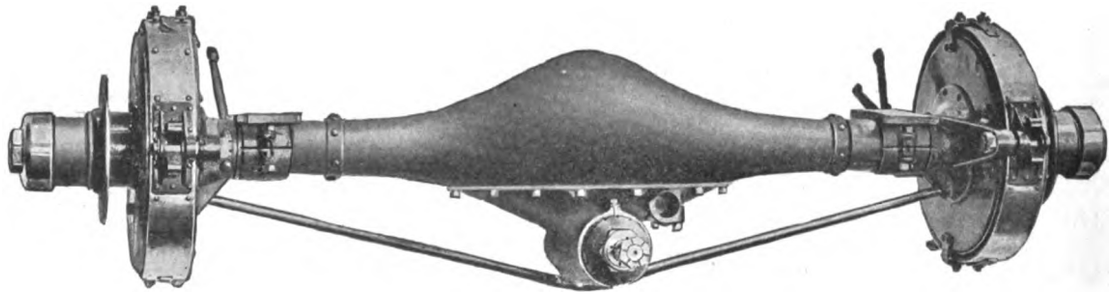
American Axles

American



Whether it be a bevel or worm drive rear axle, the *American* should hold first place both in the mind of the manufacturer and the man who contemplates buying a car.

The fact that we built and successfully introduced the first bevel drive type of rear axle in America and now lead in the production of the worm drive type, in itself proves our superiority.

American Axles both bevel and worm drive, can be furnished for cars weighing up to 4500 lbs. and to 60 horsepower.

The worm and bevel in all cases are mounted on annular ball bearings of ample size with proper thrust bearings. Hubs can be equipped with annular or taper roller type bearings, as may be specified.

TWITCHELL AIR GAUGE

The Twitchell Gauge Co. have succeeded the Twitchell-Garvey Mfg. Co. and will in the future market the Twitchell Tire Pressure Gauges.

All patents, rights, etc., including the Twitchell trade name, have been taken over by this firm. Our rights and yours will be vigorously protected under Twitchell patent No. 927,298, which has been repeatedly adjudicated as valid by the courts.

The fine quality of workmanship and accuracy which has distinguished the Twitchell Gauges in the past will be maintained in the future, and this Gauge with the new stop feature, which has been perfected by Mr. Twitchell, is now ready for the market and will thus continue to be the leading Tire Pressure Gauge, as it has been since it first was put on the market.

Mr. Fred G. Bremer has succeeded Mr. James Garvey as manager of this firm.

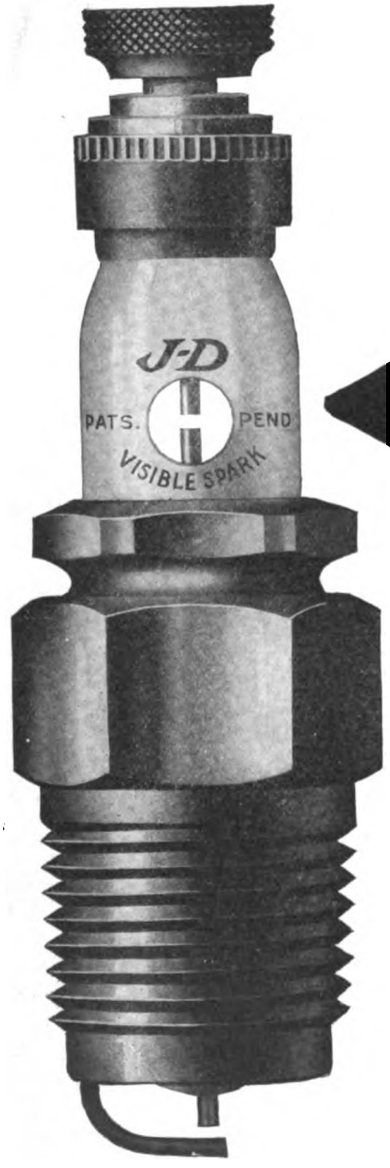
One Look Tells Everything



The JEFFERY-DEWITT CO. DETROIT, MICH. Visible Spark Plug lays bare all ignition trouble

The "visible gap" is an open "window" giving you a full view of the internal workings of your spark plug.

If the spark is seen jumping the gap, look for your trouble between the gap and sparking point.

If there is no spark in the gap, your trouble is behind the plug—in Magneto, or batteries, or coil, or wiring.

But for the "visible gap" it would take you many precious minutes—often hours—to locate the seat of trouble.

$1.00 Buys this great new Spark Plug

Indicates in which direction trouble lies.
Facilitates timing of engine.
Intensifies spark in cylinders.
Consumes only minimum current.
Gap ajdustable—can be closed entirely.
By widening gap plug cleans itself.
Permits regulating spark for any cylinder.
Costs same as any good plug—$1.00.

Dealers will find J. D. Visible in greatest demand

Visible Idea Worked Out Perfectly for the First Time

The "visible gap" feature, so far as being incorporated in a plug, has always seemed as far away as perpetual motion. The visible feature has been marketed in a separate device for years, but this is the only plug embodying the visible feature in a practical manner.

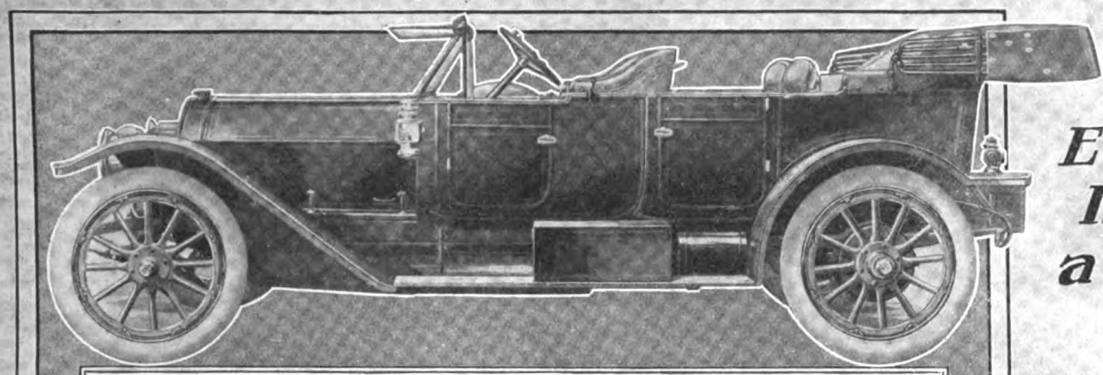
It is simple. Merely a hole in the porcelain and a spiral action to regulate length of gap in the central electrode which carries the current.

The hole in no way lessens the strength of the plug, and the current in jumping the "visible gap" loses none of its efficiency. On the other hand it intensifies the spark at the gap in the cylinder.

Additional prestige is lent the J. D. Visible Spark Plug by the fact that it is being introduced by the largest manufacturers of spark plugs in the world. We are exclusively manufacturers of spark plugs; we make millions of them each year.

The J. D. Spark Plug was a famous plug before it was improved by the visible feature. It combines finest workmanship, best materials and simplest designs.

Every part of this plug is made in our factory—even the porcelain being produced in our own potteries from clays and other ingredients imported from Europe.



This unequivocal guarantee goes with all our spark plugs:

"Your money back or a new plug if you are not satisfied"

If your dealer hasn't the J. D. Visible yet, send your money direct to us for a set, and we will ship them postpaid. Remember, the J. D. Visible Plug is only $1.00. Write today for our literature on ignition. It is free.

Not Built for Show

The Stewart Speedometer is *not* built for *show;* it's built to show how *fast* you *go.* It's never *fast* and never *slow;* it never misses a second to the hour nor an inch to the mile.

If we spent a million dollars on each Stewart Speedometer we couldn't make a more *workmanlike* instrument. The added expenditure would all go for fol-de-rols and frou-frous. We could diamond-stud the *dial*—we could gold-plate the *hands* and emblazon the *case* with sapphires, but for all the *extra* you'd pay you'd only get *display.*

The Stewart Speedometer is the most *accurate*—the most *reliable*—the most *durable* speed measure that can be made. If you give *more* for any other speedometer, you get *less.* A higher price means *"front"*—not *value.*

Not an *aristocrat*—it *works.*

Magnetic principle; jewel bearings; wearing parts hardened and polished; open dial; large figures, easily read; absolutely accurate; 100,000-mile season odometer; 100-mile trip register, can be reset to any tenth of a mile. Guaranteed for five years. Strongest flexible shaft; drop forged swivel joint; noiseless gears.

Hartford Pointers—No. 3
Reduced Depreciation—and Easy Riding

WHY is it that often one car will command a far better price on second sale than another of the same make and model—even though the first has seen longer and more severe service?

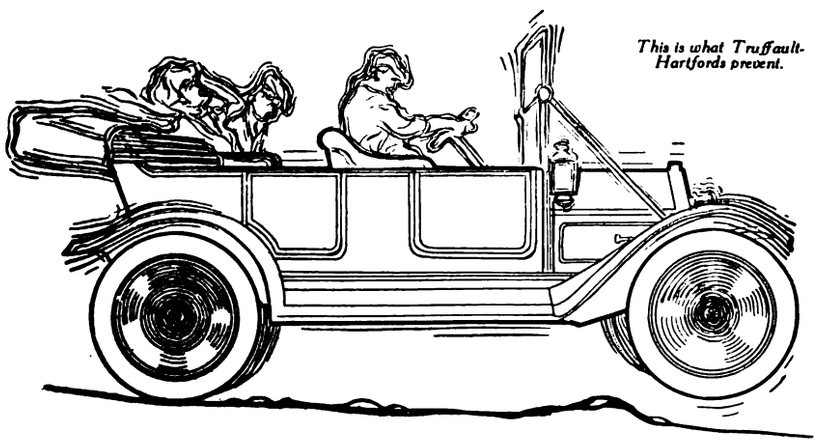
Better care—there's the reason.

No factor is more destructive to the motor and mechanism than the ravaging jolt, jar and vibration incurred on rough, tortuous roads.

You cannot avoid rough roads and get anywhere, but you *can* avoid the jolt, jar and vibration. And in so doing, you are materially adding to the life of the whole car and to its market value. The

Truffault-Hartford SHOCK ABSORBER

points the way. Experts declare that it reduces depreciation 50%. This alone should commend its use to every prudent car owner. But there are further advantages in using this equipment—advantages in comfort, safety and economical up-keep—advantages of enough consequence to more than double the pleasure of motoring and effect a large reduction in up-keep costs.



The spring plays a very important part in the performance of the car. If allowed to operate without proper restraint, it acts violently. It isn't natural that your car should pound down on its axles when it encounters a road obstruction, then rebound with distressing fury. Nor is it reasonable that the tires, engine and frame can long endure this abuse. The logical thing to do is to provide against it, and the one logical provision is the Truffault-Hartford Shock Absorber—the only device exercising *proper* control over spring action.

Proper control, in brief, means this—a steady, constant frictional resistance to *both* the contraction and expansion of the spring—enough resistance to always keep the spring within its normal working limits, but *not* enough to interfere with the *full play* that is necessary to secure easy riding.

This exclusive feature of the Truffault-Hartford accounts for its ability to completely absorb all road shocks without detracting from the flexibility of the spring. It is the reason for its efficiency in preventing spring breakage—in reducing tire, up-keep cost, and depreciation by one-half—and in making your car sumptuously easy to ride in on all kinds of roads.

Twenty-four leading automobile manufacturers equip every car they produce with the Truffault-Hartford.

Four Models—$60, $45, $25, $15.

This is what Truffault-Hartfords prevent.

Your dealer will be glad to tell you more about the Truffault-Hartford—and our new catalogue will also acquaint you with its many additional features. Write for it today.

15 Years "Weeding Out" the Inefficient.

Since 1897 when we conceived the idea of the shock absorber (six years before the device was presented to the public at large) we have "weeded out" by costly experimenting, year after year, numerous other devices, including the *wedge*, *cam*, hydraulic, air-cylinder, strap, spring, spiral spring and spring cylinder, etc. We have proved conclusively—that, so far at least, no other principle than rotary friction has come anywhere near to solving the shock absorber problem and this is mentioned that the public may take advantage of the knowledge gained at great expense during a period of 15 years.

Free Yourself From the Troubles and Expenses of Unprotected Tires

STOP the troubles before they come—save your money and enjoy your motoring. Never again need a puncture or any other tire trouble ever turn an auto ride of yours into a roadway experience of bitter exasperation and grimy repair toil. Get this tire protection—proved by thousands of motorists who have kept their tires good as new after more than two years continual service on the worst of roads with

Standard Tire Protectors

Rubber and fabric have been demonstrated the only practical meterials for tire protection. In Standard Tire Protectors the toughest rubber ever produced and the hardest woven fabric give your tires protection that protects against every form of tire injury—almost like armor plate around your tires.

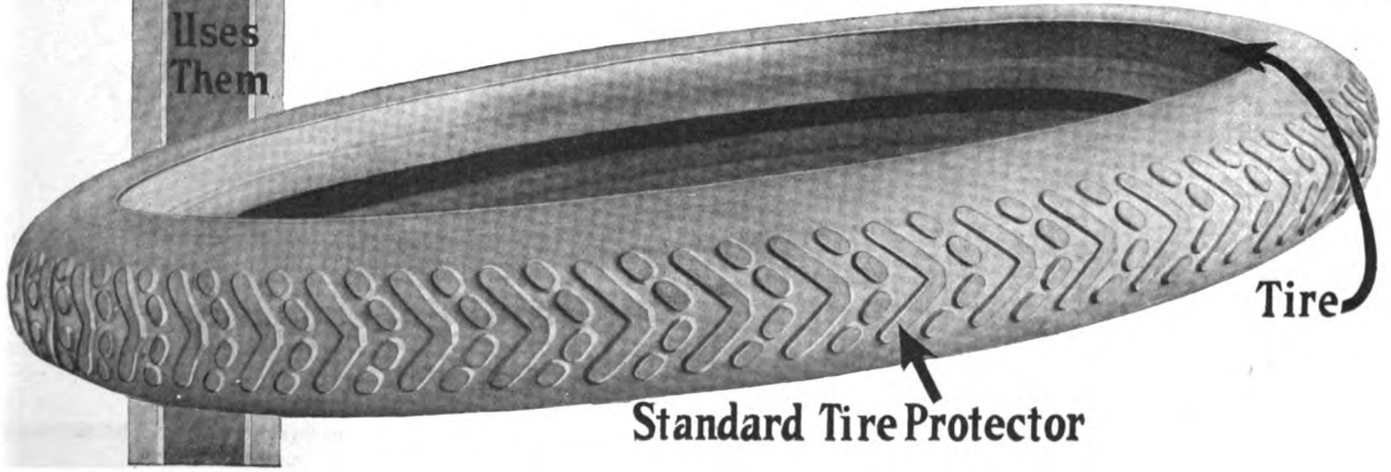
Reduced prices—average 20 per cent lower than last year on all popular sizes—a further economy gained for you by our new manufacturing advantages, now remove the last reason for you to delay giving your tires this protection. And if desired, you may have our famous non-skid tread instead of plain tread. You get skidding protection in addition to tire protection—both at the cost of one.

Standard Tire Protectors may be had in all regular sizes—to fit any tires. They are easily applied in just a few minutes—and are held on tight and fast simply by inflation pressure No mechanical attachments. Sand or gravel cannot get between the Protector and the tire.

Free Book on Tire Protection

will be sent you on request. It contains much valuable information, and proves the way for you to save ninety per cent of your motor car up-keep costs. Write for this free book now.

Dealers — Greater Discounts to You with Lower Prices to Users for 1912



Our new manufacturing equipment gives us advantages that we share with you and your customers The demonstrated merit of Standard Tire Protectors and the reduced prices for 1912 will be made known to every motorist in America by our big advertising campaign—just starting. The advance orders show you will have five calls for Standard Tire Protectors this year for every single inquiry you had last year. And the new discounts we make will still further increase your profits.

Prepare to get your share of this business. Is your 1912 order in? If not, rush it! Write for new price list and new discounts, with particulars of our advertising support to push your sales. Write us today.

After a Lighting System is Installed on a Car

the dynamo, batteries, wire, etc., last about as long as the car does. The lamps in time burn out and have to be replaced.

The car owner does not know as much about lamps as does the maker of lighting systems and therefore is liable to buy the wrong lamp when he has to replace.

He is satisfied with his first lamp and he can be kept **always** satisfied if "Federal" Mazda lamps are available for his replacements.

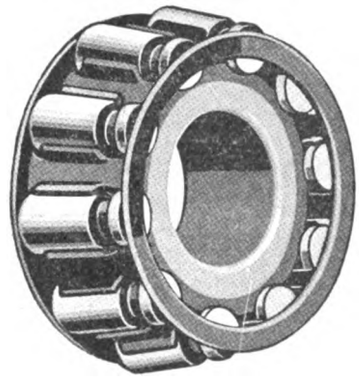
LOOK FOR THE LABEL

The Pointing Finger Shows You WHERE to Look for the Label

The reason for this is that "Federal" Mazda lamps are efficient and each lot of lamps is uniform with former lamps.

One thing is certain—the owner who uses a Federal MAZDA will always get a lamp as brilliant, economical and strong as the one he had before and many times he'll get a better lamp.

These are some of the proved reasons why dealers should carry Federal Mazda lamps and why car owners should **look for the label.**



Write for Bulletin No. 12 and quantity prices.

THE Bearing that will not wear has never been made. If you could make a motor-car bearing that would not wear you could get most any price that you asked for it. One that would stand up under the weight and the load—that would meet the tremendous side pressure called "end-thrust" which comes when corners are turned—

One that would stand all the shocks from the bumps and the ruts—yet never show wear.

TIMKEN
TAPERED ROLLER BEARINGS
Have Greatest Resistance to Wear

The Timken Bearing is made of special Timken analysis steel. The steel is carbonized and heat-treated to make its surface glass hard but not brittle.

Underneath the surface the steel is left tough and elastic to cushion the shocks.

The Load is Distributed

Load, on the Timken Bearing, is distributed over the entire length of its rollers, not concentrated at points as is the case in a ball-bearing.

This wide distribution of load keeps pressure, and hence wear, down to the minimum.

The Timken principle of tapered rollers revolving about a tapered cone with two ribs—makes a bearing that takes end-thrust at the same time it is carrying vertical load.

And the end-thrust, too, is distributed along the length of the rollers.

So, in material and its treatment—in principles of design—and in actual practice in thousands of pleasure and commercial cars—it is theory proved true, that—

Timken Tapered Roller Bearings offer the greatest possible resistance to the inevitable wear—

And, when wear does come it can, in the Timken, be entirely taken up by adjustment without the least impairment of efficiency.

The Test of Actual Service

Timken Tapered Roller Bearings are used in pleasure and commercial cars made by the great majority of American builders and are being adopted by the leading foreign builders as well.

The list of Timken users reads like a blue book of car builders. Almost every car you know is named in it.

You'll be interested to have a copy of that list. It is printed in a booklet, "The Companies Timken Keeps." Send for a copy today.

The Timken Roller Bearing Company
Canton, Ohio, U. S. A.

The only axle manufacturer licensed to make automobile axles equipped with Timken Roller Bearings is the Timken-Detroit Axle Company

My Greatest Success

By R. E. Olds, Designer

Trainloads of Reo the Fifth

In the past 25 years, a dozen models of mine have become the season's sensation.

Again and again I have seen the factory swamped, and men paying a bonus to get my latest creation.

But Reo the Fifth has broken all records. I never say a demand which compares with this.

Five cities at this writing have **trainload** orders with us —**orders for forty carloads each**—to go in a single shipment.

But the demand is just beginning. Very few men have yet discovered this car.

Soon there will be 10,000 cars in the hands of 10,000 owners. Ten thousand men will be telling others how Reo the Fifth performs.

Then will develop the real demand for this final car of mine.

Not a Passing Sensation

Other season sensations have come and gone. New cars and better came out to displace them.

Those days are over now. Reo the Fifth comes close to the limit in motor car engineering. It embodies the final results of my 25 years of experience. In every detail it marks the best I know.

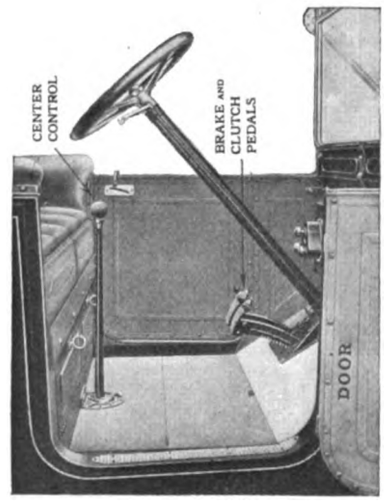
There is no probability that we shall ever see a materially better car. The years can bring only minor changes.

It Deserves It

This car deserves popularity. That is my satisfaction.

The men who buy it get the utmost of which I am capable. There will be no regrets—none to say I misled him. And none will ever see a car which gives more for the money.

The steel in this car is all analyzed. Every vital part is put to radical test.



Parts are ground over and over, to get utter exactness. Inspection is carried to extremes.

There are big margins of safety. The bearings are Timken and Hyatt—roller bearings in place of the usual ball bearings.

The tonneau is roomy, the wheels are large, the car is over-tired. The carburetor is doubly heated.

The body is finished in 17 coats. The upholstering is deep, the lamps are enameled. Even the engine is nickel trimmed.

Every part of the car shows the final touch—the avoidance of petty economies. I am proud of it. Not an iota has been omitted which could add to the worth of this car.

Center Control— No Side Levers

Then here, for the first time, we get rid of all side levers. All the gear shifting is done with this center cane handle—done by the right hand. It is done by moving this lever less than three inches in each of four directions.

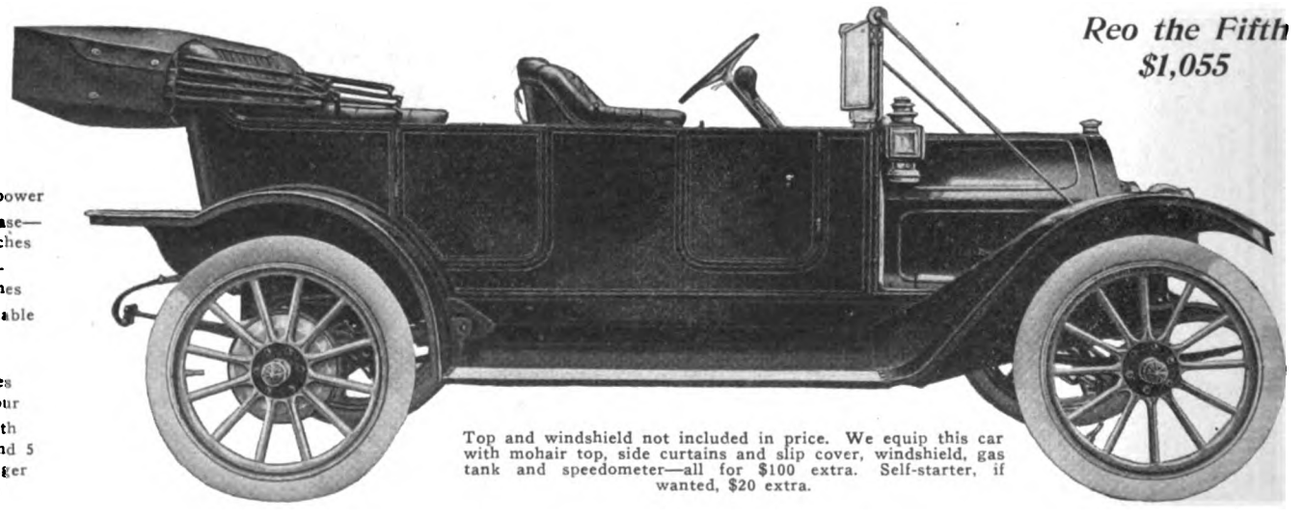
Both brakes are operated by foot pedals, one of which also operates the clutch. So the entrance in front, on either side, is clear.

This arrangement permits of the left side drive. The driver sits, as he should sit, close to the passing cars—on the up side of the road. Heretofore this was possible in electric cars only.

Thus we have solved the last important problems in designing.

Price Still $1,055

The price of this car remains at $1,055, though subject to instant advance. This price is too low for a car like this. It leaves no adequate margin.



But we shall continue this price, in all probability, until materials on hand are exhausted.

1,000 Dealers

Reo the Fifth is shown by dealers in a thousand towns. We will direct you to the nearest when you send for our catalog. Please write for it now. It shows the various bodies. Address

R. M. Owen & Co. General Sales Agents for Reo Motor Car Co., Lansing, Mich.

Canadian Factory, St. Catharines, Ont.

30-35 Horsepower
Wheel Base— 112 Inches
Wheels— 34 Inches
Demountable Rims
Speed— 45 Miles per Hour
Made with 2, 4 and 5 Passenger Bodies

Top and windshield not included in price. We equip this car with mohair top, side curtains and slip cover, windshield, gas tank and speedometer—all for $100 extra. Self-starter, if wanted, $20 extra.

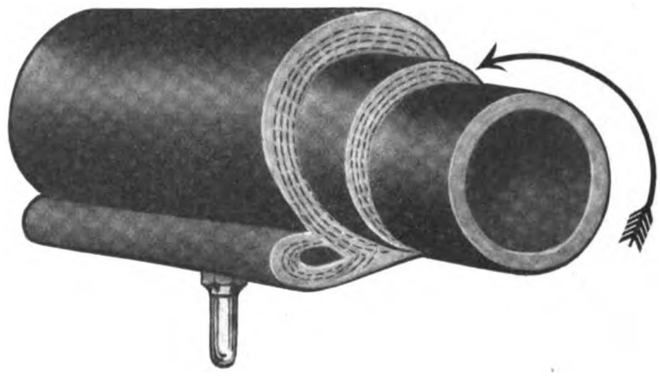
A Side Chat With Dealers

Perhaps you've been among those who said to themselves "I wonder if 'Innershu' really does do the work. I wonder if it WILL stop ninety per cent. of all punctures and prevent blow-outs."

"If 'Innershu' does do this it is a great thing and I ought to tell my customers about it."

Our claims are positive and to the point.

Over 2500 DEALERS are selling "Innershu" and making friends and money by it.



We stand back of every claim.

Replacements last year equalled less than one-tenth of one per cent.

Does it look reasonable that such a record could be established by any article that could be questioned?

"Innershu" WILL do the work. We guarantee it. Further we help our dealers—don't expect them to "go it alone."

Get a sample of "Innershu" for your own car right away. Write us today.

STOPS 90 per cent of Punctures

Prevents BLOWOUTS

Can be used with any tires. Will practically eliminate your tire troubles.

Be sure and get the genuine

"The Horn that's Made for the Discriminating"

TUTO HORN

THE TWO TONE HORN

Results That Count.

THE TUTO horn is made by Warning Signal Specialists—the best in the world. A superficial examination of the TUTO horn, its completeness and neatness of equipment, its "two-tone" feature and the one button operation is proof positive of this statement.

¶ By specializing on warning signals, we have made the TUTO horn just as you would specify, if you had spent years of study and experimenting in the use of warning signals for motor cars, only we did this work several years ago and anticipated your requirements of to-day.

¶ First, the TUTO horn does all of the signalling of the motor car, displacing the inadequate bulb horn and the duplication necessary when a second or loud warning signal of the one-note type is used.

¶ Second. The TUTO horn provides with its one button and one horn, a low-abrupt-note for regular service purposes, as well as a loud-abrupt-note for an emergency signal. It is instantly responsive and extremely easy to operate, with no confusion or juggling, as is necessary when going from a bulb to a button.

¶ Third The TUTO horn comes complete with cord and protecting fixtures, making a most neat and permanent installation and assuring a positive signal every time the button is depressed.

¶ Fourth. The battery consumption is almost negligible in comparison to other signals.

¶ Fifth. The low and the loud signal notes of the TUTO horn are purposely made distinctive to get instant attention, yet not paralyzing, so as to defeat the purpose of the warning signal or to invite adverse legislation through indiscriminate use by irresponsible drivers.

¶ The more you use the TUTO horn, the more thoroughly convinced you will become of its vital importance for standard equipment on all motor cars.

SHELDON AXLE CO.

LARGEST SPRING AND AXLE PLANT IN THE WORLD

Digitized by Google

EXPERIENCE — SHELDON — RIGHT DESIGN
FACILITIES — AXLES — RIGHT STEEL
"Made in the Largest Axle Factory in the World"

In this and subsequent issues of Motor World, it is purposed to set forth the story of a plant, and its product—the plant so gigantic and the products so well known, that it needs but a single word to tell the concrete story of achievement—

SHELDON

the name that first comes to mind when springs and axles are mentioned—the name made a by-word through sterling worth of production and tremendous volume of output—the name familiar to every man in the trade and laity who studies the specifications of standard pleasure cars and commercial vehicles.

For these reasons SHELDON products are largely self-advertised—and we say "self-advertised" advisedly, because it is patent to those familiar with trade advertising that our recent publicity efforts have fallen short of the conventional mark set by hundreds of manufacturers in this field.

Up until this time we have not found it possible to adequately tell the story—We have been busy—pushed to the wall by insistently increasing demand.

Digitized by Google

ELECTRIC SHELDON SILICO SPRINGS MANGANESE

GUARANTEED FOR LIFE

In the meantime, we have been adding shop after shop, drop forge after drop forge, furnace after furnace, lathes and drill presses by the score, until today, we point with considerable pride to a great manufacturing establishment situated in Wilkes-Barre, Pa., the heart of the Wyoming valley, where by day, gigantic pillars of steam, and by night the lurid glare of flame, marks the location of the **largest combined spring and axle plant in the world.**

And now we are going to advertise

or rather, we propose to tell a story beginning with these four pages and continuing from week to week. This story will give the "whys" and "wherefores" responsible for the existence of a plant covering fourteen acres, and employing 2,200 men, each a specialist in his line of work.

ECONOMY OF PRODUCTION: Every manufacturer in this and in every other production field sets his course by the fixed star—"Economy of production."

Competition demands it. The life of the business depends upon it.

Sometimes manufacturing economies are practised for the benefit of the ultimate user—more frequently the added proceeds go into abnormal dividends for the stockholders.

Now mark this well—SHELDON Economy of Production here set forth at length, sends its surplus right back into quality—a quality that means service for the man whose car is SHELDON equipped.

Digitized by Google

TRANSPORTATION: The SHELDON factory immediately adjoins three main lines linking east and west, north and south. A network of sidings brings the cars of raw material right into the factory and take the finished product out. We have no teaming.

FUEL: There are coal breakers within 1,500 feet of this plant. The very ground upon which it stands is honeycombed with tunnels and workings. We buy many thousand tons of coal yearly—it costs about $2.00 per ton. Figure the cost of coal delivered from 150 to 500 miles away, and form your own conclusions.

LABOR: The location of the SHELDON plants in the hard coal regions, gives us a superior personnel in the shape of men particularly fitted, through sturdy physique, to do the most and best work in the heavy processes involved in the manufacture of springs and axles.

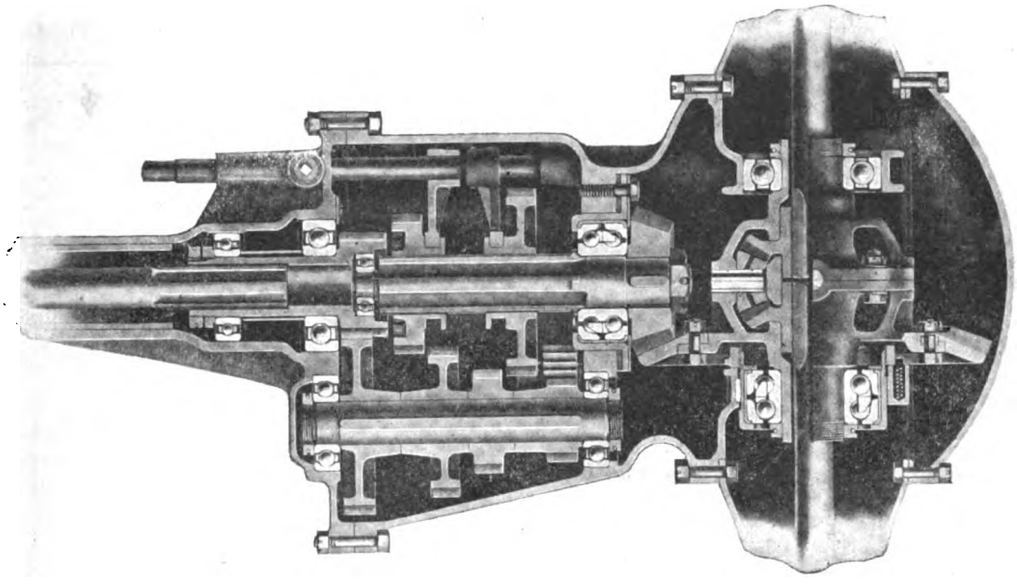
PURCHASE OF RAW MATERIALS: The SHELDON factory turns out more springs than any other concern in existence—ranging from the light carriage spring to the heaviest spring used on commercial trucks. The axle department, also a tremendous organization, produces hundreds of axles daily. It follows that our purchase of steel in the tremendous quantities necessary for these purposes, gives prices much lower than competition in our particular field.

SOURCE OF SUPPLY: This factory is closer to the steel market than any other similar plant in America, reducing transportation charges on raw material, and when you multiply the savings on one car by the savings on a great many thousands of cars, the result is pronounced.

FACTORY DETAILS: There are a hundred and one minor methods of saving made possible because this business has been reduced to such an exact science that nothing tending toward waste can escape the trained eye of our spring and axle specialists. Scientific methods obtaining here, have reduced all losses in manufacture to a minimum.

In making an introduction to an interesting story, we have but one object in mind—to thoroughly impress the manufacturer that the SHELDON economy of production is much more than a name—that is, it is one of the biggest factors in the making of **quality** springs and axles.

Years have been spent in perfecting this organization which, today, stands without a peer as a model of standardized, exact spring and axle practice, backed by an engineering staff larger and superior to that of any other concern in existence.



In every process of construction, from primal design to final polish, we put brains at a premium, and so it is that we have devised the following formula which holds good in the production of every spring and every axle leaving our factory.

Brains: Ninety per cent. Material: Ten per cent.

Next week we will begin the discussion of axles—what they ought to be, and what they frequently are not.

SHELDON AXLE COMPANY, Wilkes-Barre, Pa.

American Made FOR American Trade

New Departure GUARANTEED Ball Bearings

In Sixty Per Cent. of American Cars

SUPERIOR FOR THE TRANSMISSION: The success of New Departure Double Row ball bearings in resisting excessive radial loads and thrust stresses is demonstrated in the fact that this bearing is more commonly used than any other in the transmission back of the bevel pinion. It does away with the cumbersome thrust washer, complicated and expensive mounting and gives maximum efficiency and durability.

NUMEROUS ADVANTAGES IN THE DIFFERENTIAL: The use of the New Departure Double Row on the side of the differential insures simple, economical, ample provision for carrying the considerable thrust loads from the ring gear, fixes the working relation of the parts and prevents "slapping" of the gears. These are important advantages.

New Departure Single Row Ball Bearings are employed in the construction illustrated above, to care for radial loads only. This bearing has no superior, is absolutely guaranteed for strength of material, quality of workmanship and accuracy of finish.

THE MOTOR WORLD

Vol. XXXI New York, U. S. A., Thursday, May 2, 1912. No. 6

ALVORD TO ACQUIRE SPLITDORF

Long Pending Negotiations on the Point of Consummation—Means Removal of Splitdorf Plant to New Jersey.

Negotiations between John M. Alvord, of New York City and Torrington, Conn., and C. F. Splitdorf, Inc., of New York City, which have been in progress for several months, and which on at least two previous occasions appeared near to consummation finally have been brought to a point where only the signatures of the interested parties are necessary to convey the Splitdorf business to the Alvord interests. It is understood that these signatures will be attached on or before Saturday next.

Despite the prominence of the Splitdorf establishment and the diversified interests of Alvord, not very many persons identified with the automobile trade have been aware of the negotiations, and the transaction is likely to prove one of the real surprises of the season. Although a capitalist of great means, and the owner of the Excelsior Needle Co., The Standard Co., The Torrington Co. and other industries in the Naugatuck Valley of Connecticut, Alvord is little known to even the prominent men of the automobile industry, despite the fact that among his many possessions is The Eagle Co., of Newark, N. J., which produces windshields and other automobile accessories.

The exact terms of the contract between Alvord and Splitdorf are not public property, but it is known that they will bring a million dollars or more into the Splitdorf business and that the Splitdorf brothers, John and Charles F., will retain a substantial interest, secured by handsome blocks of preferred stock in the enlarged company which will be brought about and which will perpetuate the name Splitdorf and continue the manufacture of Splitdorf magnetos and other ignition specialties.

The deal will carry with it the removal of the Splitdorf plant from New York City to Newark, N. J., where it will be established in the former Domestic sewing machine factory, which is owned by Mr. Alvord and which now is occupied by The Eagle Co. and several other of his allied concerns, several of which will be removed to Torrington. The change of base will not be wholly unwelcome to the Splitdorfs as, during the past year, they have suffered severely from the effects of a strike which resulted in a reduction of their working day from ten to eight hours, thereby upsetting their estimates and greatly affecting both the cost and quantity of their productions and placing them at other disadvantages. In New York City also, the Splitdorf industry is scattered in three separate buildings, which likewise has its inconveniences. In Newark, the entire plant will be housed in one building and with favorable labor conditions and working hours it is anticipated that the benefits that will accrue will be widely felt, the Alvord capital and influence, plus the Splitdorf experience and reputation being a combination that cannot fail to exert far-reaching effect.

Willys Assumes Gramm Presidency.

Having acquired control of the Gramm Motor Car Co., of Lima, Ohio, John N. Willys has formally assumed the presidency thereof. He was elected to the office at a meeting held in Lima last week, at which time George W. Bennett, Willys's right hand man, who is vice-president of the Willys-Overland Co., became treasurer of the Gramm corporation and R. J. D. Keplinger, secretary. B. A. Gramm remains one of the five directors, and with Max Bernstein and the three officials named constitutes the board.

Hewitt Men on International Board.

E. C. Converse and Ambrose Monell, directors of the Hewitt Motor Co., of New York, which recently was taken over by the International Motor Co., have been elected directors of the latter corporation. Converse, who is president of the Bankers' Trust Co., also has succeeded W. D. Sargeant as chairman of the International board of directors.

WANTS $150,000 FOR HIS SERVICES

Found Buyer for $5,000,000 General Motors' Notes but Hitch Developed—General Motors Makes Certain Admissions.

When the case of Horton vs. General Motors Co., which has been placed on the May calendar of the New York Supreme Court, comes to trial, Harry L. Horton probably will discover just where the General Motors Co. ends and where the General Motors Securities Co. begins. Horton is suing the General Motors Co. for $150,500, not wholly on his own account, but as the assignee of one Neil MacDonald, who claims to have rendered services to the big corporation which was worth the large sum which he specifies, the service consisting in having found a purchaser for $5,000,000 worth of General Motors 6 per cent. gold debentures.

According to the complaint, the service was rendered between January 1, 1910, and December 1 of the same year, during which period MacDonald was "devising and advising concerning plans for the raising of money to meet the defendant's needs by the sale of its securities." On or about March 18th MacDonald claims that he arranged for the sale of the debenture bonds to the value of $5,000,000, to Tucker, Anthony & Co., of New York, at an agreed price of 89, the prospective purchaser relying upon the truth and accuracy of the General Motors financial condition as disclosed by itself. This statement, it is alleged, showed that the total liabilities of the General Motors Co., and its constituent companies, exclusive of capital stock, amounted to $7,500,000, when, as a matter of fact, they were in excess of $15,000,000. By reason of this and other alleged misstatements, Tucker, Anthony & Co refused to purchase the debentures unless they were protected by a mortgage on the Buick or Cadillac plants, or other adequate mortgage security, which, however, the General Motors Co. refused to execute and the deal fell

Digitized by Google

through. It is for work he did in this connection, and the consequent disappointment and loss due to the failure of the deal to be consummated, that Horton, as assignee of MacDonald, believes he is entitled to $150,500. The odd $500 represents traveling expenses incurred by MacDonald in prosecuting his operations.

Its answer, which is sworn to by W. C. Durant, vice-president of the General Motors Co., practically serves notice on Horton that he is "barking up the wrong tree," and that instead of suing the General Motors Co., his action should be leveled at the General Motors Securities Co. In his affidavit, Durant admits that he entered into negotiations with MacDonald and requested him to render service, not to the General Motors Co. but to the General Motors Securities Co., which then was in process of formation and which thereafter was formally organized, the understanding being that MacDonald's compensation would be paid by the General Motors Securities Co. and would amount to 25 per cent. of the half-interest owned by the General Motors Co. "in the net profits of the said General Motors Securities Co. from the handling of such securities as should be sold and paid for" during the period between March 1 and June 1, 1910. The General Motors Co. also admits that it gave to Tucker, Anthony & Co. an option, expiring April 1, 1910, to purchase certain of its notes which were to be issued, and that in doing so it submitted to that firm a statement showing its financial condtion as to September 30, 1909. As Tucker, Anthony & Co. did not exercise the option, or enter into any contract with the General Motors Co., through no fault of the latter, it is alleged, the General Motors Co. denies liability and asks that the suit be dismissed.

Creditors Take Over Grabowsky Truck.

Having over-extended itself, the Grabowsky Power Wagon Co., of Detroit, found itself in such difficulties that its creditors were called together in Detroit last week in an effort to relieve the pressure. About one hundred creditors were represented at the meeting, at which it was disclosed that the Grabowsky liabilities aggregate $405,000 and its assets $1,250,000. After thoroughly discussing the situation, a plan was formulated whereby a committee of four, representing the largest creditors, will take charge of the business and conduct it until the present obligations have been discharged. As soon as this is effected, the company will be turned back to its stockholders. The committee consists of W. K. Pruden, the wheel manufacturer; H. W. Chapin, of the Brown-Lipe-Chapin Co.;H. S. Firestone, of the Firestone Tire & Rubber Co., and B. F. Tobin, of the Continental Motor Mfg. Co. While the plan of action has been agreed to by a majority of the creditors, several formalities remain to be concluded before it becomes effective, but there is no doubt that the measure of relief adopted will be consummated.

BACKER BRINGS DOWN DORIAN RIM

His Banking Troubles Finally Entail Receivership for Rim Company—Efforts to Refinance It Prove Vain.

Efforts to save the Dorian Remountable Rim Co., of New York, and to prevent it from following its president and financial sponsor into the bankruptcy court, which at one time seemed practically assured, finally proved vain, and on Thursday last, 25th inst., three creditors joined in a petition asking that the company be adjudicated a bankrupt. In response to the petition, Judge Mayer, in the United States District Court for the Southern District of New York, appointed Joseph M. Conklin receiver, under a bond of $40,000. Later, on Saturday last, 27th ult., Martin D. Henkel, Arthur D. Alexander and Joseph S. Josephs were appointed appraisers and permission was given the receiver to sell the office furniture and fixtures.

The petition alleged that the Dorian liabilities are greatly in excess of $200,000, while the assets, at a fair valuation, do not exceed $100,000. Offers for the sale of the business in its entirety had been made but they were far from satisfactory, and as one of the creditors had given notice of his purpose to prosecute his action to judgment the petitioning creditors applied for a receiver in order to conserve the best interests of all.

The Dorian company's failure is directly due to the personal entanglements of M. Rosett, its president and backer, who conducted a chain of private banks in New York and other states, all of which were patronized chiefly by working people and foreigners of the humbler class. These banks went to smash early in March last, at which time Conklin was appointed their receiver. He also took charge of the Rim company as part of Rosett's assets.

At the time of the bank failures, it was feared that, although in a prosperous condition, the Rim company would be involved in the trouble. Strenuous efforts were made to refinance it and place it on its feet, independent of Rosett, and success appeared likely, but several obstacles interposed which could not be overcome; and, for the best interests of all, the receivership proceedings were instituted.

According to counsel for the petitioning creditors, Rosett has invested $97,000 in the stock of the Dorian company, and in addition has loaned it $200,000. He, therefore, figures as the largest creditor. The other liabilities are said to aggregate only $15,000.

Muskegon Motor Plant to be Continued.

Reports that the Muskegon (Mich.) plant of the Continental Motor Mfg. Co. will be abandoned when, in July next, that company takes possession of its immense plant which now is nearing completion in Detroit, are emphatically denied by President Tobin. He states that while the general offices and the entire headquarters staff will be removed from Muskegon to Detroit, the plant at Muskegon will be operated as a branch factory, and that in view of the present demand for Continental engines there is no thought of shutting it down.

Three Added to Henderson's Staff.

L. S. French, C. K. Share and F. E. Wilson have become identified with the Henderson Motor Car Co., of Indianapolis, which recently was organized by R. P. Henderson and of which he may be president. Like Henderson himself, French formerly was with the Henderson Motor Sales Co., when it distributed Cole cars. He served as advertising manager but resigned about two months since to enter the piano business in the West. He has returned to Indianapolis, however, and will be a stockholder and secretary of the new Henderson company. C. K. Share, who previously was with the Willys-Overland Co., will become treasurer of Henderson's new enterprise, of which Wilson will be the sales manager. Formerly Wilson occupied the same position with the Marion Sales Co.

Suit Involving Imported Axles Settled.

Just as it was due for trial in the New York Supreme Court, the suit of the G. J. G. Motor Car Co., of White Plains, N. Y., against the Krefeld Steel Co., of Krefeld, Germany, was amicably settled this week. The trouble grew out of a purchase of Krefeld axles which the G. J. G. company claimed were not according to specifications and which, because of their failure in actual use, caused injury and damage to the American company. In its answer, however, the Krefeld Steel Co. set up a counterclaim on the ground that the axles had not been paid for. As the case was settled out of court, the merits of the several allegations were not gone into.

Overland Completes Its Big Addition.

The four-story 300x400 foot concrete addition to the Willys-Overland plant in Toledo, Ohio, has been completed and the necessary machinery now is being installed. It is expected that with the added facilities John N. Willys's projected output of 25,000 cars during the present year will be attained, 16,000 of them having already been built and shipped. The high water mark of 900 cars a week was touched two weeks since.

Billings & Spencer Discontinue Middlemen.

After having continued for some two years, the selling arrangement whereby Claire L. Barnes & Co., of Chicago and Detroit, marketed the product of the Billings & Spencer Co., of Hartford, Conn., has been discontinued. As was the case before the arrangement was effected, the Billings & Spencer Co. will market its forgings and tools direct to the trade.

Digitized by Google

MARCH'S INCREASE 56 PER CENT

Exports Continue Upward Trend—Revolution-Ridden Mexico Only Country That Shows Much Reduced Purchases.

After attaining a new high record in January, which was still further increased the following month, it is not strange that the exports of American automobiles and parts should feel the pace and slow up slightly during March, though the net total still shows a substantial gain over the same months one year ago; the figure for March, 1911, was $1,638,947, whereas during the corresponding month this year $2,549,348 worth of cars and parts were shipped out of the United States. The gain amounts to $910,401, which represents an increase of approximately 56 per cent. Of this total sum $2,125,565 represents the value of 2,222 complete automobiles, last year's figures being $1,364,402 for 1,510 cars. The remainder, $423,783, represents the value of parts, as against $274,545 for the month of March, 1911. The average value per exported car increased from $837 in 1911 to $956 in 1912. Last month is was $946.

As was the case last month, all but two of the twelve geographical divisions mentioned in the government statistics increased their purchases, Canada leading as usual with an increase of $148,854 over the figure for the corresponding month last year, which was $778,402. Germany and Italy, which last month were the only countries to show a decrease, both show a substantial increase this month, the figures being $40,335, as against $14,494, and $33,893, as against $29,016, respectively. The United Kingdom and revolution-ridden Mexico are the two divisions which this month exhibit decreases, the loss in the case of the former being $16,164 and $48,665 in the case of the latter; the figures for the month of March, 1911, were $330,223 and $61,161, respectively. British Oceania was the third heaviest purchaser and took $334,376 worth as against $83,894 for the same period last year, which is the greatest increase listed.

For the nine months ending March, 1912, 14,569 complete cars, valued at $14,189,948, and parts to the value of $2,850,047 were exported, bringing the grand total up to $17,039,995, as against $9,837,181 for the corresponding period last year; the actual gain was $7,202,814. Complete details are shown by the subjoined table.

Slight Drop in Exports of Engines.

For the month of March, the exports of automobile engines were slightly lower than the figures for the previous month, 831 complete engines valued at $102,010 being shipped to foreign countries, as against 954 engines valued at $113,871, which were exported during February. At the close of the nine months ending March, 1912, the total number of engines exported during the period was 4,315 and they were valued at $519,318. As the government statisticians did not list automobile motors separately until July, 1911, comparative figures for the corresponding period of last year are not available.

Hartford Suspension Takes Up Plugs.

Having developed and taken up the production of an electric lighting and engine starting device, it is not so surprising as otherwise would be the case that the Hartford Suspension Co., of Jersey City, N. J., manufacturers of the famous Truffault-Hartford shock absorbers, should embark in the production of spark plugs. At any rate, the Hartford company has done that very thing, and although its plug is not quite ready for market, it is known that it is of the two-piece type and that it will be of the same quality that characterizes the other Hartford productions.

American Tires Continue Foreign Gains.

The exportation of American-made tires retained its strength during the month of March, the shipments attaining a value of $228,098, as compared with $131,183 for the same month last year; the gain is $96,915 and represents an increase of 74 per cent. During the nine months ending March, 1912, $1,869,471 worth of American tires were exported to foreign countries, the figures for the corresponding period of the year before being $1,325,903. The increase is approximately 41 per cent.

LOCKWOOD SURVEYS FOREIGN FIELD

Regal's Returned Export Chief Talks of Conditions Abroad—Where America is Weak and Where Strong.

R. M. Lockwood, who recently completed almost a globe-girdling tour in the interests of the Regal Motor Car Co., had the unique experience of passing through the scene of the Italian-Turkish war, the Chinese revolution and the Mexican uprising, to say nothing of having witnessed the Durbar in India.

In China, Lockwood found the Chinese particularly partial to American motor cars, but the field is limited, as the use of automobiles is confined almost exclusively to Shanghai and Tien Tsin. None of the other large cities have suitable streets or roads. In Egypt also automobiles can be used only in the cities of Cairo and Alexandria. There are no suitable roads elsewhere. There are few cars in Egypt and most of the few are of either English or French manufacture.

"In India I found the roads excellent, but nearly all the cars are of English make," says Lockwood, in summarizing his observations. "The dealers themselves are Englishmen and it is difficult to overcome their prejudice against American productions. These same conditions exist in Ceylon, though the field for automobiles is somewhat more limited.

"The people of the Straits Settlements and Malay States are favored with very good roads. Their dealers also are Englishmen, but contrary to the usual rule these Englishment seem to look with favor on the American automobile. Our cars are generally popular and many of them are in use. In Java there are a large number of motor cars, considering the small European population. This is due principally to the fine roads and general prosperity. The makes of cars represented include the products of practically all the countries manufacturing automobiles and no one nation can be said to control the market.

"In the Philippine Islands the American

manufacturers, not unnaturally, dominate the field, and in spite of the poor roads there are a great many cars owned in Manila and the largest cities. The future for American cars on the islands is very bright. This statement is equally true of the situation in Japan, though the people there prefer the small American touring car to the larger models. At present the use of automobiles is largely confined to cities like Tokyo and Yokohama. While the roads are good they are too narrow, but the fact that the government has recently appropriated a large sum of money for widening the roads, makes it seem quite probable that in time motoring will become very popular throughout the Mikado's dominioins."

Babcock Backbone of Buffalo Merger.

Beliefs that the Babcock Electric Carriage Co. constituted the backbone of the recently organized Buffalo Electric Vehicle Co. were confirmed this week when the identity of the units of that million dollar merger, or holding company, were made public. The Babcock company heads the list, the others being the Clark Motor Co., the Buffalo Electric Carriage Co. and the Buffalo Automobile Station Co., the latter of which operates one of the largest and most completely appointed electric garages in the country.

The new corporation, which has acquired the capital stock of the four companies, will amalgamate the business of the several establishments and prosecute their affairs on a much enlarged and more aggressive scale.

Having acquired the capital stock of each of the subsidiaries, the officers of the Buffalo Electric Vehicle Co., whose identity first was made public in the Motor World last week, have been elected officers of the several units. They are as follows: Samuel J. Dark, president; A. A. Landon, vice-president, in charge of manufactures; William A. Morgan, vice-president, in charge of sales; Harry Yates, treasurer, and Alfred W. Thorn, secretary.

The preferred stock of the corporation, to the amount of $300,000, has been wholly underwritten by a Buffalo syndicate and a large part of it disposed to residents of Buffalo. The unsold portion will be offered for public subscription during the present month.

Concerning the conduct of the business itself, little or nothing is obtainable. J. W. Van Allen, the attorney for the company and one of its directors, who, for the time being at least, is its mouthpiece, is not prolific of information, and the other officers will say even less than Van Allen.

Grabowsky Leaves Alden Sampson.

Morris Grabowsky, vice-president of the Alden Sampson Co., of Detroit, which is one of the United States Motor Co.'s possessions, has resigned that office. He has made no plans for the immediate future, and probably will "rest up" for a while.

BIG HATS AT N. A. A. M. MEETING

Talk of Their Effect on Limousines Enlivens Its Affairs—Truck Dimensions and Demonstration Charges Advised.

Though the business of adopting standard lengths and widths for motor truck frames occupied the greater part of the attention of the members of the executive committee of the National Association of Automobile Manufacturers, who met yesterday in regular monthly session, in New York, and this serious business was further augmented by the election of the Federal Motor Truck Co., Detroit, Mich., to membership, a humorous twist was given the proceedings when a Western manufacturer arose and declared in all seriousness that the growing size of women's headgear constituted a real problem in the designing of closed car bodies, and maintained that the subject was worthy of consideration. The prevailing style in hats, he said, necessitated such a "spread" and the "creations" protruded so far upward or backward that it has become difficult to design limousine bodies to meet their needs. Most of the members viewed the matter rather mirthfully, and it finally was suggested that the maker in question constitute himself a committee of one to visit the leading milliners and ascertain what the forthcoming styles in hats were likely to evolve.

As regards the standard truck frame sizes that formally were adopted, two widths—36 inches and 42 inches—and 20 lengths, graduated by feet and half feet were agreed upon, the figures being as follows: Inches—48, 60, 72, 84, 96, 108, 114, 120, 126, 132, 138, 144, 150, 156, 168, 180, 192, 204, 210, 216.

The object in recommending these frame dimensions is to provide standard widths and lengths toward which manufacturers can work with a view to providing for interchangeability of bodies on trucks of different makes and models in the future and to enable the body builder to make up stock bodies that can be delivered without delay and placed on any make of truck. The desirability of such standards is shown by the fact that measurements of 88 different models by various manufacturers presented 19 different widths, from 28 to 46 inches, and that upward of 100 models showed 41 different lengths of frame back of seat, from 48 inches to 218 inches. By graduating the lengths by multiples of 6 inches, from 4 feet to 18 feet it was found that these could be reduced to 20 lengths.

The question of the desirability of making charge for commercial vehicle demonstrations also came up for discussion and resolutions recommending the following charges were adopted: ½-ton truck, $10 a day; 1-ton truck, $10 a day; 2-ton truck, $15 a day; 3-ton truck, $20 a day; 4-ton truck, $25 a day; 5-ton truck, $30 a day; 6-ton truck, $30 a day; 7 and 8-ton trucks, $35 a day; 9 and 10-ton trucks, $40 a day.

Quinby Relinquishes Isotta Agency.

After having combined the business of body building and selling the Isotta-Fraschini cars in this country for several years, the J. M. Quinby Co. finally have relinquished the imported production and hereafter will handle only American cars—the Simplex and the S. G. V. The Isotta-Fraschini agency for the United States has been transferred to a new company, the Isotta-Fraschini Motors Co., which just has been organized with $25,000 capital and which yesterday took possession of the premises 1849 Broadway, New York, the Quinby store at 54th street and Broadway being relinquished. Quinby & Co., however, will continue to build the bodies for the Isotta cars and their Simplex and S. G. V. cars will share the salesrooms of the new company.

The officers of the Isotta-Fraschini company are: G. M. Heckscher, president; G. E. Parker, vice-president; G. M. Thurber, second vice-president and general manager; C. B. Jaqua, secretary-treasurer. G. M. Heckscher, the president of the company, is a son of the well-known mining man of that name, with whom Jaqua also has been associated; G. E. Parker, the vice-president, is an attorney, and the second vice-president, G. M. Thurber, who will be general manager also of the Isotta-Fraschini Motors Co., has been serving as manager of the Quinby car department, and his new office is merely in the line of continuing his work.

Imports Hold Their Renewed Strength.

As was the case last month, when for the first time in three years, imports of automobiles into the United States showed increased shipments from each of the four leading manufacturing countries of Europe, similar advances are shown for the month of March. The total figures for the month amount to 69 cars valued at $161,263, as against 48 cars valued at $92,206 for the corresponding month last year. The increase represents a gain of 48 per cent. in the number of cars imported and 75 per cent. in their value. The respective quantities are as follows:

Imported from	No.	Value.	No.	Value.
United Kingdom..	8	$17,314	9	$27,511
France	22	39,644	42	96,783
Germany	3	5,976	4	11,282
Italy	4	6,631	5	6,666
Other countries...	11	22,641	9	19,021
Total cars.....	48	$92,206	69	$161,263
Parts of.....		$28,623		$28,020
Total cars, parts		$120,829		$189,283

The figures for the nine months ending March, 1912, show that 786 cars, valued at $1,733,639, and parts valued at $240,212 were imported as against 634 cars valued at $1,342350 and parts to the value of $240,-868 for the corresponding period last year.

Charles Kellogg is about to open a garage in Centerville, Ia.

Bunn & Goembel is the style of a new garage firm in Pipestone, Minn.

A new garage is to be opened in Fulda, Minn., by F. W. Johnson.

Emerick Bros. and S. Childers are building a new garage in Medford, Ore.

Charles Taylor and Perle Schenck have opened a garage in Pomeroy, Ia.

The Orland (Cal.) Garage has been purchased by Tom and Roscoe Scribner.

August Schierenbeck has sold the St. Mary's Auto Garage, of St. Mary's, O., to Stafford Noble.

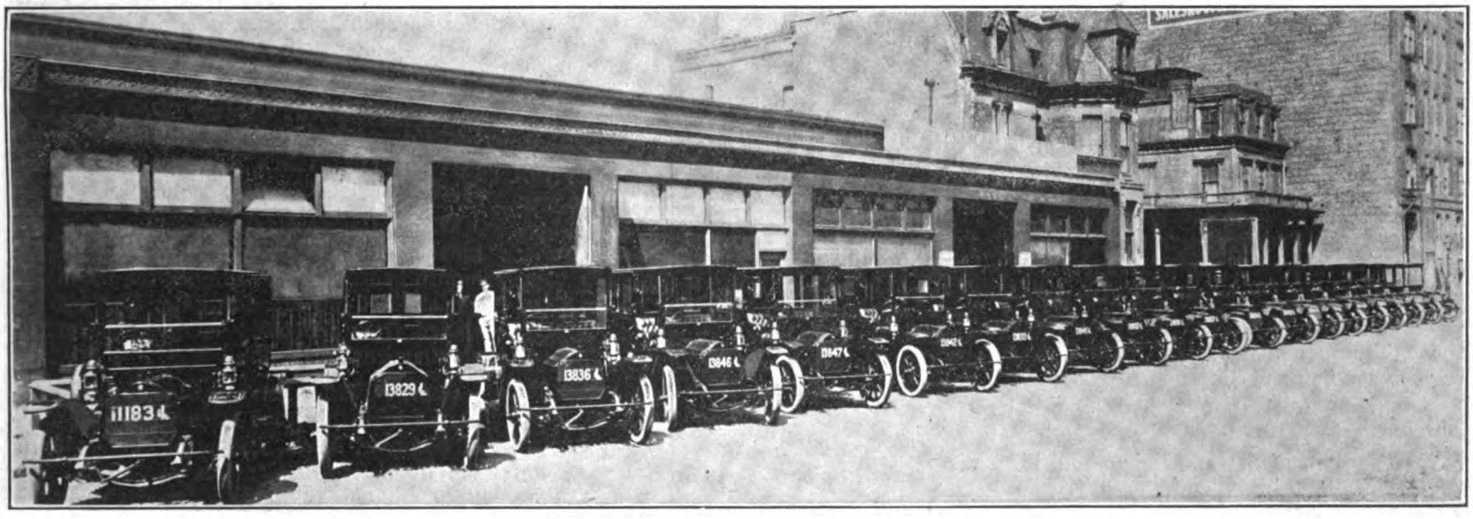
A garage in Dinuba, Cal. It is 44 x 64 feet and is nearly ready for occupancy.

A new garage, 50 x 125 feet, is to be erected at Flandreau, S. D., by John Ingvalson, the town's blacksmith.

Amos L. Harris and L. B. Giddens have formed a partnership in Jacksonville, Fla., where they will sell Velie cars.

The Creston Implement Co., of Creston, Ia., has sold its automobile department to George A. Anderson, of Massena, Ia.

Two physicians, Dr. Arthur H. Cutter and Dr. Harry H. Nevers, will build a garage at 343 Broadway, Lawrence, Mass.



The Grundy Motor Sales Co. has been

Diego, Cal., have secured the agency for Oakland cars and will establish a garage and salesroom.

W. C. Morehouse and Malcolm Parrott have opened an automobile livery in Poughkeepsie, N. Y. They will operate as Morehouse & Parrott.

D. E. Kelly, owner of the Clinton (Ia.) Auto & Supply Co., has sold out to the Model Auto Co., which will operate both establishments.

The Grand Garage, at Santa Rosa, Cal., formerly conducted by C. F. Reynolds, has been purchased by R. J. H. McKee, B. Kent and Robert Taffinger.

FRANK PARMELEE CO.'S FLEET OF GARFORD CARS THAT PLY FOR HIRE IN CHICAGO

J. A. Anderson has laid the foundations for a garage and machine shop in Jamestown, N. D.

Jean H. Duffy has opened a repair shop and a garage at 820-824 Julia street, New Orleans, La.

Phillips & Taylor, Owosso, Mich., will open a garage and place several taxicabs in service.

F. L. Geiger, of Manchester, N. H., has embarked in the garage business in Sanbornville, N. H.

A garage covering four city lots is to be erected in Fresno, Cal., by W. H. Ackerman; it will cost $9,750.

McDonald & Fountain is the style of a new firm in Hawley, Minn., which sell and repair automobiles.

The American Auto Supply Co., of New York has opened a Chicago branch at 1408 Michigan avenue.

Thomas Thorpe is erecting an iron gar-

organized in Los Angeles, Cal. The firm members are C. Fred, W. and J. R. Grundy.

A new garage is to be opened in Azusa, Cal., in Center street near Azusa avenue, by George W. Knight and Ralph N. Burt.

Meeker, Col., is about to become possessed of its first garage. It is being built by H. H. Joy, the city's water commissioner.

The Vickman Auto Co. has been organized in Minneapolis, Minn., to distribute Auburn cars. It has located at 311 Third street.

A half interest in the McPherson (Kan.) Motor Co. has been purchased by Milan Riddell, who will enter actively into the business.

Joseph R. Sutterly has opened an exchange for second-hand cars in Trenton, N. J., at South Clinton avenue and East State street.

H. B. Young and W. F. Lloyd, of San

E. J. Montigny, of Brooklyn, N. Y., who has the Long Island agency for the Stutz car, has removed from 33 Grant Square to 1289-1291 Bedford avenue.

Stoffel & Bosustow, who conducted a garage and automobile agency in Racine, Wis., have dissolved partnership. Bosustow will continue the business.

Clinton R. Foutz, who has been prominent in the automobile affairs of Baltimore, Md., has launched into the trade. He will handle the Havers "six."

D. S. Padelford, of Minneapolis, Minn., is about to engage in the garage business in Roseburg, Ore. A building, 80 x 100 feet, is being erected for him.

The Motor Truck Corporation has been organized in Washington, D. C., and is located at 1719 H street N. W. It will handle Alco and Little Giant trucks.

The Auto Tire Service Co. has commenced business in Passadena, Cal., with

Digitized by Google

R. A. Thompson as manager. It is located at 13 South Garfield avenue.

E. A. Bennett, in Washington, D. C., has formed the Crawford Automobile Sales Company and will handle Crawford cars. His quarters are at 1615 O street N. W.

M. E. Humbarger and Samuel Hoover, of Toledo, Ohio, have formed the Collingwood Sales Co., and will sell Apperson cars. They have not yet secured a location.

R. C. Hathorn, formerly an employe in H. A. Perkins & Co.'s garage in White Rover Junction, Vt., has bought out his employers and will continue the business.

T. W. Thompson has purchased the G. A. Bull garage in Santa Cruz, Cal. The sale takes with it the agency for Overland, Kissel, Maxwell, Stoddard-Dayton and Reo cars.

The Locomobile Co. of America has established a branch in San Francisco, which is in charge of J. M. Page. It is located in temporary quarters at 942 South Grand avenue.

Charles A. Malley, who recently resigned from the King Motor Car Co., of Detroit, has secured the New England representation for the Universal truck and is preparing to open a salesroom in Boston.

The Kansas City Garage Men's Association has been organized with the following officers: President, B. B. Huckell; vice-president, Charles Brooke; secretary, Myran Albertson; treasurer, P. D. Warshner.

The Williams Automobile Co., agents for Metz cars, which has been doing business at 343 Trumbull street, Hartford, Conn., has removed bag and baggage to Bristol, in the same State. Its Bristol address is 49 Church street.

T. A. Vernon, in Salem, O., has sold his interest in the Vernon and Seran Garage to the Salem Auto and Repair Co. E. A. Seran is manager of the new combination. Vernon, however, retains the agency for Everitt cars.

Lee D. and Burton L. Jamieson, in Toledo, O., have taken the Oldsmobile agency for Northern Ohio and are erecting a two-story brick building in Huron street for their business. They will operate under the firm style Jamieson Bros.

W. E. Wood, of Holyoke, Mass., for some time connected with the Farr Alpaca Co., is, with Frank Lamont, of Springfield, preparing to open a garage in Palmer, Mass.

M. B. Crosby has started an automobile and repair business in Calais, Me.

F. Carleton Dole, of Worcester, Mass., who is described as an automobile salesman, has filed a voluntary petition in bankruptcy. He schedules liabilities of $22,497, of which $20,997 is unsecured. He places his assets at $50.

The Louisville Lozier Co., has commenced business in Louisville, Ky., at 708-712 West Broadway. Howard Lothrop, of Detroit, is manager, and H. M. Martin, of the same city, is in charge of the service department. Lozier and Pullman cars will be handled.

The H. E. Wilcox Motor Co., of Minneapolis, has established a branch in Kansas City, at 1325 Walnut street, which will have charge of the distribution of Wilcox trucks in the entire Southwest. R. E. Chamberlain, assistant sales manager of the company, has assumed charge of the branch.

The International Motor Co., maker of the Mack, Sauer, and Hewitt trucks, has established a branch in Washington, with offices and salesrooms at 811 Seventeenth street N. W., and a service department at Fifteenth street and Ohio avenue. John S. Larcombe, Jr., is in charge as manager.

Myer Abrams & Co., of Boston, who have been prominent in the New England horse trade, have embarked in the motor truck business, handling the Lauth-Juergens truck. J. J. Gormley, who formerly was connected with the Lozier branch in Boston, has been engaged to manage the truck department.

The Federal Rubber Mfg. Co., of Milwaukee, has established branches in St. Louis and Minneapolis. The former is in charge of L. E. Allmon, at one time manager of the Frey & Magill Motor Supply Co., of Denver. The manager of the Minneapolis establishment is E. S. Johnson, who will have the title northwestern sales manager.

Four new automobile buildings are going up on the old Luna Park property in Pittsburgh, Pa. They are of iron and reinforced concrete and will house the Franklin Automobile Co.'s branch, the White agency, the Goodrich tire branch, and the International Motor Co. Each will be 48 x 128 feet and is expected to be ready for occupancy September 1.

Carrigan Bros., of Los Angeles, Cal., who for several years have been agents for the Midland and Pratt-Elkhart cars, have retired from the business. In conjunction with W. A. Peck, who formerly was connected with the Midland factory, they have organized the Carrigan-Peck Mercantile Co., which will do a general merchandising business in Los Angeles and the surrounding country.

M. C. Harvey, of Tampa, Fla., is endeavoring to organize what will be styled the Tampa Auto Supply Association. It is designed to prove one of those co-operative organizations, which will supply owners with accessories at trade prices, or thereabouts, in return for a fee of $5 per year. He has opened an office in the Greeson Theatre Building in order better to prosecute the undertaking.

The Universal Motor Truck Co. of New York, which has had the metropolitan agency for the Universal truck, has been taken over by the parent Detroit company and henceforth will be operated as a factory branch. F. K. Parke, of the parent company, has become president of the New York corporation, of which H. H. Walton, former president, is vice-president and general manager. Samuel Mann is treasurer and George Wheeler secretary.

On the petition of the Wabash Realty & Loan Co., the Central Trust Co. of Indianapolis, has been appointed receiver for the Indiana Automobile Co., of that city. Crawford Fairbanks, a Terre Haute brewer, is president of the Realty company and one of the principal owners of the automobile concern and is named as a defendant in the suit. It is alleged that the automobile company owes the plaintiff $8,000 on a $10,000 note, made January 9, 1907, and endorsed by Fairbanks. The debts of the company are said to mount high, but it is claimed that it has property enough to cover its indebtedness. According to one of those concerned, the suit is a friendly one, which probably will result in winding up the Indiana Automobile Co.

Changes Among Prominent Tradesmen.

H. E. Partridge, for several years connected with the Boston branch of the Ford Motor Co., has been transferred to the Ford branch in Buffalo, of which he has become the manager.

George H. Brown, who recently engaged as manager of the Century Electric Motor Car Co., of Detroit, has resigned that office. He has taken a position with the Mather Spring Co., of Toledo.

W. H. Campbell, the one-time chief engineer of the Willys-Overland Co., who last month became identified with the engineering staff of the Flanders Mfg. Co., has resigned from the latter company. He has another iron in the fire.

George Waller, who previously was connected with the Argo Electric Vehicle Co., of Saginaw, Mich., and prior thereto with the Regal Motor Car Co., of Detroit, has been appointed Michigan branch manager for the Ignition Starter Co. He will have charge of the Disco sales in the State of Michigan, including the city of Detroit.

John W. Hill has been appointed "sales engineer" for the Bantam Anti-Friction Co., of Bantam, Conn. Until recently Hill, who is a mechanical engineer, was connected with the Browne & Sharpe Mfg. Co., of Providence. Previous thereto he had experience with the General Electric, Westinghouse and American Locomotive companies.

Recent Losses By Fire.

Duluth, Minn.—Cadillac Automobile Co., damaged. Loss $40,000.

Jenkintown, Pa.—John S. Newbold's garage, damaged. Loss, $2,500.

Great Falls, Mont.—Montana Motor Car Co.'s garage, damaged. Loss, $46,000.

Boston, Mass.—Hub Automobile Co., 93-97 Freeport street, building damaged. Loss, $20,000.

New York City—H. Lambert's garage, Central Park west and 100th street, partly destroyed. Loss $20,000.

WEED AGAIN "TIES UP" CHANNON

Secures Sweeping Order Restraining Production and Sale of Anchored Tire Chains—Atlas Chain Also Affected.

Having obtained an injunction in Wisconsin restraining a purchaser from using tire chain parts made by the H. Channon Co., of Chicago, the Weed Chain Tire Grip Co. returned to the United States District Court for the Northern District of Illinois and took action against the Channon company itself. In that court a suit already was pending for infringement of the Parsons-Weed patent, but by this move, which was made last week, the Weed people succeeded in securing a new preliminary injunction order which effectually ties up the Channon output of tire chains and parts until the main issue is decided.

The order, which was granted by Judge Sanborn on Thursday last, 25th ult., directs that pending the determination of the suit the Channon company, or anyone connected therewith, shall not make, sell, use or cause to be made, sold or used tire chain grips infringing the Parsons' patent for parts thereof, or parts or material adapted and intended for use in connection therewith, and from otherwise infringing or contributing to the infringement of said letters patent; and "in particular from making, selling, using or causing to be made, sold or used the Shero, Gripwell, Rufshod, Zig-Zag or other chain grips" of similar types, whether the grips are provided with straps or extra lengths of leather or chain whereby they may be anchored on the wheel, or whether or not such grips be sold with instruction sheets or notices advising or directing a purchaser to "anchor" them to the wheels by such straps or extra pieces of chain or leather.

This order of Judge Sanborn answers the several defenses which have been made by the Channon company which, in August, 1911, was enjoined from infringing the Parsons-Weed patent, but which later in the year challenged the Weed company by placing on the market the Rufshod, Gripwell and Zig-Zag grips, and offering them for sale with extra pieces of chains, which were called "anchors," and which were designed to prevent the tire chain from creeping on the wheel. It also sold parts of tire chains, announcing that they were to be used only for the manufacture and repair of grips that were provided with "anchors," in the belief that by giving such notice its tire chains and parts could not be treated as an infringement of the Parsons-Weed patent.

Judge Sanborn, however, repeated his ruling made in a previous suit against another company, to the effect that the furnishing of the "anchors" was "simply a subterfuge to evade the rights of the patent owner."

Not the least interesting feature of the proceedings before Judge Sanborn was the introduction by counsel for the Channon company of a modified form of Atlas grip, which he stated the Atlas Chain Co., of Brooklyn, N. Y., was about to place on the market, and as the Channon company wished to sell it he asked the court to so word the injunction order as to exclude the proposed Atlas grip from its operations. This the court declined to do, however, not only granting the order in the sweeping form, as stated, but expressly saying that it did include the modified form of Atlas grip exhibited.

Court Dismisses Rose's Patent Suits.

For lack of prosecution, the suits instituted by the Rose Mfg. Co., of Philadelphia, against the Emil Grossman Co. and eleven other New York concerns for alleged infringement of the patents covering the Never-Out license plate holder, have been dismissed by Judge Mayer, sitting in the United States District Court for the Southern District of New York, in which the action was instituted in December last. The twelve defendants entered prompt appearance to the Rose suit and later filed a demurrer, but as the Rose company failed to argue the demurrer, or alter its complaint, or take any other action, Judge Mayer dismissed the suits but placed the costs on the defendants. The defendants who were joined in the complaint and in the defense are as follows: Emil Grossman, Emil Grossman Co., Eclipse Specialty Co., National Sales Corporation, Motor Car Equipment Co., Gus Balzer Co., American Auto Supply Co., Lowe Motor Supplies Co., J. Alexander Mfg. Co., John J. Treacy and George F. Connelly (trading as Universal Auto Supply Co.), William Wooster (trading as Automobile Surplus Stock Syndicate), and Joseph H. Parsons.

To Build Fisher Bodies in Canada.

To reproduce on Canadian soil the well-known Fisher bodies, the Fisher Body Co., Ltd., of Canada, has been organized with $150,000 capital stock and will locate in Walkerville, Ont. It already has acquired a four-acre site in that city, on which will be erected a brick plant which it is expected will be ready for occupancy about July 15th. The incorporators are: Fred J. Fisher, Charles T. Fisher, L. Mendelssohn and A. Mendelson, who will be the principal stockholders and who also are the principal stockholders of the Fisher Body Co., of Detroit.

Tall Yarn of Daimler American Plant.

Although press dispatches state that the parent Daimler company in Germany has completed negotiations for a plant in Niagara Falls, N. Y., officials of the Daimler Auto Import Co., of New York, state that they know nothing whatsoever regarding the matter and take no stock in the report. They say that it is wholly unlikely that a Mercedes factory would be established in this country without their knowledge.

GARDEN SHOW IS NOT YET ASSURED

Broad of Trade's Exclusive Contract With Grand Central Palace a Factor in the Case—Existing Situation.

Routine business only was transacted at the regular monthly meeting of the Automobile Board of Trade, which was held yesterday at its New York offices. The matter of shows and the forthcoming conference of sales managers, which it is well settled will occur during July, were discussed, but the discussion developed little of general interest.

While it is practically assured, the projected amalgamation of the Board of Directors with the National Association of Automobile Manufacturers did not enter into the considerations of the meeting, as the conference committees of the two associations have not yet outlined the necessary plan of action.

Subsequent to the meeting of the Board of Trade directors, however, the Association Patents Co., which is the legal repository for various patents owned by its members, held its annual meeting, at which these officers were elected; Charles Clifton, president; C. C. Hanch, vice-president, and Alfred Reeves, secretary-treasurer.

The Board of Trade show committee, Col. George Pope, Alfred Reeves and M. L. Downs, also convened, and as a result it is known that despite statements to the contrary the Board of Trade has not yet taken a new lease on Madison Square Garden for show purposes. The new owners of that building, who will perpetuate its existence for another year, at least, have invited the Board of Trade to hold a show in the famous structure next January, but there are several serious formalities to be observed before any lease can be executd. Ultimately the building may be used, but if so it will be due to the grace of the lessees of Grand Central Palace, with whom the Board of Trade has an exclusive contract.

If the projected merger of the A. B. T. with the N. A. A. M. is brought about, the former will promote all shows, in which connection it transpires that at least one of the good and sufficient reasons why the show in Grand Central Palace last January was held under the auspices of the N. A. A. M., although the Board of Trade held a lease of the building, was due to the fact that the latter organization had an exclusive contract with Madison Square Garden authorities which required that the organization confine itself to that building.

Picard Gets Gray & Davis Account.

Having discontinued their New York branch, Gray & Davis, Inc., of Boston, Mass., have transferred their account to the A. J. Picard Co., of New York, who have been handling the goods on an agency basis.

Subscription, Per Annum (Postage Paid) $2.00
Single Copies (Postage Paid) . . . . . 10 Cents
Foreign and Canadian Subscriptions $3.00
Invariably in Advance.

Postage Stamps will be accepted in payment for subscriptions. Checks, Drafts and Money Orders should be made payable to The Motor World Publishing Co.

☞ Change of advertisements is not guaranteed unless copy therefor is in hand on SATURDAY preceding the date of publication.

Contributions concerning any subject of automobile interest are invited and, if acceptable, will be paid for; or, if unavailable, will be returned provided they are accompanied by return postage.

Cable Address, "MOTORWORLD," NEW YORK.

Entered as second-class matter at the New York Post Office, November, 1900.

NEW YORK, MAY 2, 1912

DEMAND THAT OVERWHELMS ENGINEERS.

It has long been an axiom that the public must be given what it wants, and the motor car business is no exception to the rule. If a manufacturer insists upon building something the public does not want, he is reasonably sure to join the ranks of the commercially unsuccessful, regardless of the intrinsic merits of his product. Were the public gifted with engineering discretion the situation would be different; but unfortunately it is true that prejudice or lack of knowledge, or both, sometimes cause the suppression of designs which, though actually of no little merit, require such development as is impossible without the active co-operation of those who buy.

A well known motor truck engineer cites, as a case in point, the horizontal motor with two opposed cylinders, stating as his own experience that a commercial vehicle with a motor of this type can be manufactured and sold at a price considerably lower than that of a four-cylinder car of the same power and carrying capacity and of the same quality, and that his two-cylinder machine was the most satisfactory, regardless of price considerations. But a combination of circumstances which included the unsatisfactory performance of many other makes of motors of this type and the increasing leaning toward four-cylinder motors, made it impossible to sell enough of these cars to justify their production, and it became necessary to refuse repeat orders from previous purchasers.

While in many cases the difficulty of properly distributing the mixture to the cylinders and of lubrication has been underestimated by manufacturers, to the evil repute of this type, other makers have been successful in solving the problems and making the most of the compactness and other good features of the opposed cylinder engine; but the handicap has been too heavy, and even in small commercial cars the four-cylinder motor is far in the lead.

While it is a matter of regret to engineers that the lay public, comparatively uninformed, should wield so much power, there is some consolation in the fact that a really good thing rarely can be permanently suppressed. It is probable that in time the public will become educated, if not to the point of technical proficiency, at least to an appreciation of the judgment of highly trained engineers, and that much that now is kept out of sight because it is not the fashion will be brought to light and its latent advantages fully developed.

HILL CLIMBING FOR PHOTOGRAPHIC PURPOSES.

Publicity undoubtedly is a good thing; assisted by photographs, publicity oft-times is made better and more emphatic; but it is unfair, to say the least, to misrepresent a machine's ability, whether by direct statements or by photographs which are deliberately "manufactured" to make a car appear to be doing that of which it is incapable. Such things are reactionary in their effects, for it is difficult to accept without question any statement or claim made by an agent making use of photographic misrepresentations. Furthermore, the attempted deceit almost invariably is uncovered, in many cases by the carelessness of the perpetrators themselves.

The trick of tilting a photograph to make a level look like a hill or a hill look steeper than it really is is not new, but it has given way to more elaborate work, such as hoisting a car half way up an impossible bank with block and tackle and photographing it, afterward painting out the hoisting gear; or blocking the wheels with stones which subsequently are obliterated from the picture, so that the car can be represented as climbing the grade under its own power. But paint can be, and often is, washed off, disclosing the fake, and the photographs actually have been sent out—and are being carefully preserved—in which the rocks under the wheels have been left just as they were photographed, in mute contradiction of the spirited caption written on the back of the print. In one case the obliterating artist carefully covered the hoisting ropes with painted foliage, but left the big pullies and hooks sticking straight out in front of the forward axle, under the impression that they were part of the car. Such a crude method as cutting a car out of one photograph and pasting it in a startling position in another is not uncommon, but is easily detected owing to the peculiarly sharp outlines.

While pictures of cars climbing at angles of 45 degrees—100 per cent.—may attract a few gaping stares, and possibly the attention of an intending purchaser, they are sure to do much more harm than good in the end, and it is inconceivable that their use should be sanctioned by responsible officers of motor car companies. But while it may be somewhat difficult to keep some press agents down to prosaic facts, it is unnecessary to do more than tell the truth about a really good machine in order to interest those whose interest is worth attracting. And while the misleading photograph is not by any means in general use, and its use is not confined to America, there is no good excuse for it at all.

GASOLENE GOES UP ANOTHER CENT

Fourth Increase Makes Advance of 44 Per Cent. Within Six Months—"Reasons" That Do Not Explain.

The price of gasolene has gone up another cent and now stands at 13 cents per gallon delivered at garages. The Standard Oil Co. made the advance on Thursday last, 25th ult., and the Texas Co., an independent, at about the same time. It is the fourth increase that has been made within six months, the price late last fall being 9 cents. Little satisfactory information regarding the reasons for the advance of 44 per cent. in less than half a year is obtainable. At the offices of both the Standard Oil and Texas companies, they talk sagely of supply and demand governing prices, but nowhere is it possible to discover that the supply has decreased or the demand increased to an extent even mildly approximating 44 per cent.

According to several explanations made by J. I. C. Clark, the official medium between the Standard Oil Co. and the public, Providence and the automobile are to blame—the former because the supply of crude oil has fallen off; the latter because the demand for gasolene has increased.

"Supply and demand," said Clark on Friday last, when asked why the increases had been made. "Good crude oil, yielding a good per cent. of gasolene is falling off in quantity of production and the demand for gasolene is increasing. It has increased ever since the automobile industry began to grow and is still increasing."

Mr. Clark was asked if the raises were not arbitrary, if they were not a recuperation resultant upon the recent difficulties of the Standard Oil Co. with the Federal government.

"No," he reiterated; "it is simply because of supply and demand."

"Has the demand increased so greatly within the last few months as to warrant the increases that have been made, and has the supply fallen off so markedly as is indicated in the recent advances?" he was asked.

"There must be fifty automobiles a day made in the United States," vouchsafed Clark, in an inquiring tone.

He was informed that his guess was well within the limit and that one manufacturer alone has announced his intention of building 75,000 cars this season.

"Is that so?" remarked the oil man, with a tinge of astonishment in this tone.

Asked for facts as to production, methods of manufacture, manners in which prices are made and other data connected with the making of gasolene, Clark explained the system and gave his reasons for the change in supply.

"There are several oil fields," he said. "These produce crude oil, a substance something like molasses, which is taken from the earth, out of wells. This oil is the basis of gasolene, kerosene and other similar products. The crude oil is piped to refineries and is distilled. The first of the products which comes off during distillation includes gasolene; after that comes kerosene and the others.

"It is singular," he added, "but the Pennsylvania and West Virginia field produces the best grade of crude oil and this field was the first discovered.

"There are other fields in Texas, Mexico and California. I do not know just what will be our production of crude oil this year. Last year I believe it was something like 218,000,000 barrels. Although gasolene and crude oil have been increased in price the comparative production will probably appear inconsistent in that it may be greater than the supply of last year. This, however, is because the quality of the crude oil is not as good as was that of last year. The Pennsylvania field, of which that in West Virginia is a part, gives the best oil and the percentage of gasolene obtained from a good grade of the crude product will run from 8 to 10 or 12 per cent. With the falling off in the quality of the eastern oil the southwestern fields are called on to help out and the oil there is not of as good quality. The per cent. of gasolene obtained in that part of the country is, I should say, 3 or 4 per cent.

"Thus you can see that if the eastern fields show the greatest falling off in production and the gasolene has to be extracted from the Texas and other oils of that section the crude oil production may be large but the quantity of gasolene may be lessened."

"How are prices fixed and who fixes them?" the Standard Oil publicity man was asked.

"That is done by the refiners," he said. "They know the conditions and know how the supply compares with the demand. If they find there is a great call for a product and that they are not producing as much as formerly or as much as they should produce to equalize matters, they are able to ascertain the relations between the supply and demand."

"But the refiners do not fix the price of gasolene, do they?"

"No," responded Clark, "I suppose the board of directors passes on all such matters."

"Is it not true that the increases may have been arbitrary because of the recent trouble of the Standard Oil Co."

"O, no," was the answer, "that is not the case. As I stated before, the demand has increased and the supply has fallen off."

"But here's a thing," almost exclaimed Clark, "that people who write about these things seldom say anything about: Whenever the wholesale price goes up a cent the retailer or garage man raises his prices about two cents. In any ordinary business if a man can make a profit on a commodity of 25, 40 or 50 per cent. he thinks it is pretty good but the garage men sell gasolene for about twice as much as they pay for it. They make 100 per cent. profit. I have a friend who lives in New Jersey and he has a tank near his garage. He can buy gasolene from a Standard Oil wagon for 13 cents, but when he comes to New York and buys it of a garage he has to pay 22 cents."

"But," interrupted the Motor World man, "is there a prospect of another raise in the wholesale price?"

"I really can't tell," said Clark. "There are some things I can't find out myself.

"And about this Texas raise," he continued, "I am connected with the Standard Oil Co. of New Jersey, and so do not know anything about the affairs of the Texas company or the New York company."

"How about lubricating oil? Is that going up?"

"That I don't know, either," was the oil man's answer. "I often try to find out things like that, but there isn't anyone around here who will give me such information."

April 29-May 4, Burlington, Vt.—Burlington Merchants' Protective Association's annual show in State Armory.

May 4, Santa Monica, Cal.—Santa Monica road race.

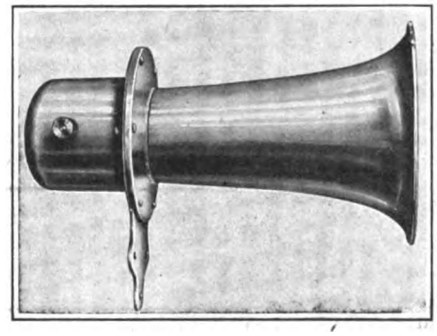
DOW TO TRY EIGHT-WHEEL TRUCK

New Yorker Acquires Rights Under Molesworth Patent and Will "Feel" Market —Odd Positioning of the Wheels.

Unless the signs fail, or the experiments which soon are to be made do not correspond to the sanguine expectations of the inventor and the performanec of models, the commercial vehicle field soon will be invaded by a brand new type of motor truck which it is expected will mark a distinct era in the industry. The Dual Wheel Co., which was incorporated last week under New York laws with $300,000 capital, and of which Alexander Dow is the moving spirit, will produce the vehicles, which will be distinguished as among the first of their kind to be equipped with eight wheels instead of the usual four. The patents under which the vehicles will be produced were issued several years ago to Guilford L. Molesworth, whose mechanical engineer's "pocket-book" is more or less well known to the engineering fraternity, and have been purchased by the Dual Wheel Co.

When seen by a Motor World man, Dow would not predict when the vehicles might be expected to put in an appearance, though he explained that work on an experimental vehicle would be commenced shortly with which to feel out the market and determine whether a demand for the truck could be created. The purpose of the unique construction of the vehicle is two-fold. It is expected to eliminate skidding—it is given out that Molesworth's real efforts in originating the design were to produce a vehicle that would not skid under the most adverse conditions—and also to reduce vibration due to uneven road surfaces to the minimum. To these ends, each axle carries two wheels at each extremity instead of one, the two wheels of each pair being mounted close together at the ends of a short spindle arranged at right angles to the main axle. Consequently the spindle becomes as a lever of the second class, whose arms are of equal length. The construction follows closely that which has been used for a number of years in Pullman cars, in fact, the theory being that as one of the wheels of a pair mounts an obstruction the other remains on level road and the total vertical movement of the truck frame is reduced by one half. It is pointed out that as dual rear tires are the rule rather than the exception anyway they might better be placed on separate wheels and advantage taken of the principle which has been outlined.



Cut-Out Tabooed by Scotland and Ireland.

Following the example set by the authorities in London, both Scotland and Ireland have promulgated orders prohibiting the use of the exhaust cut-out. In Scotland, the secretary issued the order, which went into effect last week, and in Ireland the local government board followed suit. Both orders are framed along the same general lines as the one which now is in force in London.

Fitzgerald Takes Up Horn Manufacture.

There are many persons who, while appreciating the desirable qualities of motor car signal horns of the type in which sound is produced by the mechanically induced vibration of a diaphragm, hesitate to buy because of the necessarily high price of some of these devices. This state of affairs has resulted in the production of horns of simple construction and low cost, the most recent of which is one that has been designed by the Fitzgerald Mfg. Co., of Torrington, Conn., well known as manufacturers of sheet metal articles, spun brass and copper-asbestos gaskets.

The new horn has the distinctive outward appearance of its class, and the actuating

FITZGERALD'S ELECTRIC HORN

mechanism is of the utmost simplicity, consisting of a pair of electro-magnets which, when energized by a current from a battery, set up rapid vibrations in an iron armature to which is connected the tapper or hammer which strikes the steel diaphragm. The operating mechanism has all the simplicity of the "works" of an ordinary electric bell, and is thoroughly protected from dust and dampness by a spun brass cap held in position by four screws; when this cap is removed all the working parts are exposed. The diaphragm is securely held between a flange which forms the base of the horn and a plate which is extended at one side to form an attaching bracket; these parts are securely riveted together so that there is no danger of their coming apart. The simplicity of the horn will enable the makers to sell it at a low price, and the same characteristic feature makes for long life.

Factory Secured for Sewell Wheels.

Having increased its capital from $60,000 to $300,000, the Sewell Cushion Wheel Co., of Detroit, of which H. J. Sewell is president, has acquired a new factory in that city, of which it will take possession this week. It is located at the corner of Tenth and Fort streets, and will permit the really serious manufacture and marketing of the cushion wheel which bears Sewell's name.

DIESEL TRUCK ENGINE IS COMING

Famous Inventor, Now Visiting America, Makes the Assertion — Dissipates Notion Regarding Weight of His Motor.

That there are not only abundant possibilities of the ultimate development of the Diesel engine to the point where it can be successfully employed for road vehicle propulsion, despite the general impression to the contrary which prevails, but that its actual employment for such work may be looked forward to as an accomplished fact of the very near future, is the assertion of Dr. Rudolph Diesel himself, who invented the engine which bears his name and who has labored long and persistently to bring it to its present state of perfection.

"Within a year," said Dr. Diesel to a Motor World man in an interview at the Hotel Manhattan in New York City yesterday, "or a year and a half at the outside, the Diesel engine will be used as the motive power for commercial vehicles for road use." And anyone who could look into Dr. Diesel's bright blue eyes and sense his indomitable perseverence and his remarkable proclivity for forging ahead in the face of setbacks that would cowe the ordinary mortal would have little reason to doubt the outcome of the asseveration.

In appearance, Dr. Diesel, who is a doctor of engineering and of science and a director in the Verein Deutscher Ingenieure, suggests but little his German origin. Of medium height and inclined to spareness, his clear-cut features are rather those of the successful merchant. His blue eyes, continually alert, peer through gold-rimmed spectacles, and he possesses the faculty which has been remarked in so many other persons of inventive genius of perceiving without the necessity for lengthy explanations the gist of the business in hand. In diction, his English is perfect, as becomes a man of eminence throughout the civilized world, though it is spoken with a decided Teutonic accent that is not without charm. His willingness to talk, and to make certain that nothing is misunderstood, is in marked contrast to the reticence of many another person of considerably less importance.

"As to whether or not the Diesel engine will be employed in the near future for the lighter types of pleasure vehicles," he continued in response to a query, "I cannot say, though there is no reason why it should not be so employed. But that it will be used, and very much sooner than generally is supposed, for commercial vehicles there is no question; it is a certainty. It is no longer a question of whether it can be done or not; it is simply a question of when I can get at it to complete the work. At present I have not the time. So much of my time is taken up with the larger motors—motors for ship propulsion principally—and with locomotive work, that I

Digitized by Google

can do little else at present or in the immediate future."

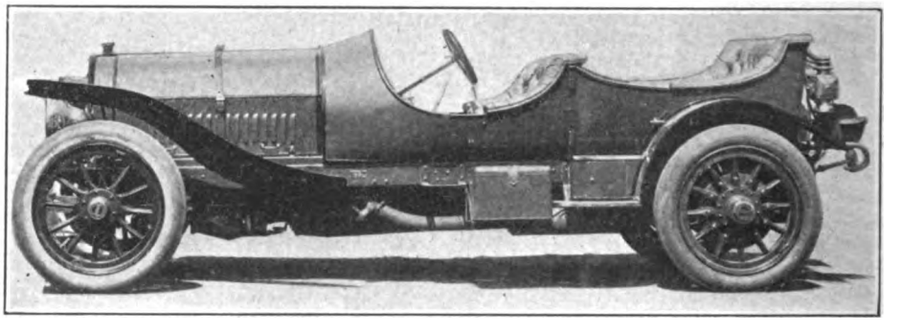
"But it has been said that present types of Diesel engines are entirely too heavy and cumbersome for automobile work. Is there any truth in the statement?" asked the Motor World man.

"That is all wrong," replied Dr. Diesel. "There is absolutely nothing in it. The first engines undoubtedly were very heavy and even present types designed for stationary work are very heavy, but our high-speed engine, which but recently has been perfected is no heavier than the average automobile motor of the same power. I have at present under test a high-speed four-cylinder engine that develops 30 horsepower at from 600 to 800 revolutions a minute and it is not a bit heavier than the ordinary 30-horsepower gasolene engine."

"If the weight can be kept down as low as is necessary, what then constitutes the difficulty?" he was asked.

"There is no difficulty," he replied. "It is simply and wholly a question of getting at the work to make some very minor alterations and as soon as I can get time to attack it I intend to do so."

It is doubtful if there are many persons in the automobile and allied industries who are not familiar with the principle on which the Diesel engine operates—a principle, which, at the time of its discovery in 1897 was declared by gas engine experts all over the world to be absolutely new. The engines are built in both two and four stroke types and will burn any hydrocarbon from the very heaviest of crude oils to ilighter distillates. One of the later developments is that even animal and vegetable oils may be utilized for fuel, excellent results having been obtained with both castor and palm oils.



As has been stated, the cycle of operation of the engine is exactly the same as any other internal combustion engine. Instead of compressing a homogeneous mixture of fuel and air, however, only pure air is compressed. The compression is carried to the point where the air becomes sufficiently heated to ignite the fuel, which is pumped into the cylinder after compression is complete, the injection being continued during a portion of the working stroke. Thus ignition difficulties are eliminated and scavenging is most efficacious for the simple reason that it is effected with pure air and not with vaporized fuel and air.

All of which and a great deal more which was of a more or less technical nature was emphasized by Dr. Diesel at an illustrated lecture which he delivered before the American Society of Mechanical Engineers on Tuesday evening, 30 ult., the lecture being given under the auspices of the Gas Power Section of the society. Before the lecture, which was of importance, if for no other reason than that it marked the first time that Dr. Diesel has appeared to the American public, he was presented with a beribboned certificate making him an honorary member of the American organization.

VANDERBILT'S IDEA OF A BODY

Not Straight Lines but Sweeping Curves His Preference for Speed Cars—Unusual Design the Result.

At this time when the straight line motor car body is so distinctly the prevailing style, anything which has a fore-and-aft curve gets at least two glances, particularly when it is known that the designer's intention of avoiding straight lines by a reversion to pronounced curves was deliberate and at the behest of a man of great wealth and of more or less prominence in the world of fashion, as is the case with a body which has been built for the six-cylinder Alco chassis which W. K. Vanderbilt, Jr., drove as a raceabout last year and will be used this season with the new body. It is of the so-called tourabout type, having a low-seated tonneau, the design being worked out according to the ideas of the owner and, as the accompanying illustration shows, is marked by low-sweeping curves which cut the sides very low, in harmony with the low seats, the raked steering column and the general aspect of raciness that the car possesses. From the deep skuttle dash the lines dip backward so sharply and deeply that the sides are cut too low to make a door necessary for entrance to the front seat, and so no door is provided; the rear seat is reached through doors that are hinged on the forward sides. The usual running boards are replaced by small steps. A sharp lateral flare is given to the front fenders, the front ends of which are narrowed somewhat, still further increasing the unusual appearance of this unusual car. Apparently the idea has been to produce a car which, while capable of carrying passengers in the rear seat, still is unmistakably intended for speed, and withal is reasonably comfortable and attractive in appearance.

VANDERBILT'S ALCO "SIX" EMBODYING HIS OWN IDEAS

Birmingham Buys Motor Fire Apparatus.

The enterprise which has within late years characterized the city of Birmingham, Ala., and which has led that city to style itself the "Pittsburgh of the South," has cropped out in a new channel and the city now is claiming to have the largest number of motor-driven fire-fighting machines of any city in the world. Birmingham has had sixteen motor-driven hose wagons, and with the addition of two more, scheduled for this week, the number will be eighteen.

Drove Without Glasses—10 Shillings Fine!

In Sydney, which is "overseas" in New South Wales, a motorist recently was arrested and fined 10 shillings because he neglected to wear spectacles when driving his car. Not that the particular magistrate who imposed the fine has a predilection for personal adornment in the form of glasses. When the driver applied for a license, according to the Motor Traffic Act he wore glasses. Later, the zealous police authorities "spotted" him driving along the public roads without them. Ergo: He was incompetent to drive, and though he excused himself with the plea that the glasses were undergoing necessary repairs, the magistrate was adamant and tacked on a further fine of five shillings because the driver had left his license at home as well.

Eye Doctor To Essay Six Months' Stunt.

As a result of a dispute between an eye doctor of Trenton, N. J., and a hardware merchant of Mount Holly, which also is in New Jersey, the eye doctor, H. Benton Young, expects to start in an automobile June 1st to do certain things within a certain time, and if he does them the hardware man, William B. Kumpl, is to hand over the snug sum of $5,000. The eye doctor is to travel from Maine to California and return within six months and to earn $10 in each town in which he registers, failing to perform which stunt he is to pay over $5,000 instead of receiving it.

Can't Alter Color of License Plates.

In Wisconsin the hideous contrast between the colors of many car bodies and the color of the State license tag evidently induced someone to believe that the Attorney-General of the State could grant permission to alter the plate to a color more in harmony with the car. The permission was asked for, at any rate, but the Attorney-General has denied the appeal and handed down a grave and solemn decision that the color of the license plate is a part of the official design.

"CLASSY" FIELD FOR SANTA MONICA

Free-for-All Will Bring "Stars" Into Conflict—Two of Five Events Abandoned—Two Cars Questioned.

Undoubtedly, Los Angeles, which is another way of saying Santa Monica, will witness some great racing on Saturday next, 4th inst. But great though it may be, it will not be quite so great as was anticipated, for lack of entries required the abandonment of two of the five events which had been programmed. They are the 202-mile race for cars between 301 and 450 cubic inches, and the 252½-mile event for machines from 451 to 600 cubic inches. The three events which will be run are two class C events for non-stock cars, with piston displacements betwen 161 and 230 cubic inches, and between 230 and 300 cubic inches, which two events will be run over courses of 101.004 and 151.506 miles, respectively, and a class D event, a free-for-all number, over 303.012 miles, circuiting the course 35 times.

These three events filled fairly well, but as usual, the chief interest will attach to the free-for-all which will go for 303 miles, and in which Berna Oldfield will make his reappearance and measure pace with men of such reputation as Bert Dingley, David Bruce-Brown, Theodore Tetzlaff, Caleb Bragg, Ralph DePalma and Louis Disbrow. Earle Cooper, who is not unknown to fame on the Pacific Coast, and David Lewis, who still has a reputation to acquire, are the others who will line up in the big event.

Robert Evans and J. Tower, who are entered to start in the second class C non-stock car event, may not start—not for lack of desire on their part, but because, unless the technical reports made to the contest board of the A. A. A. are far wrong, the Flanders cars, which they are due to drive, are Flanders in name and outline, but not in engine. While the piston displacement of the Flanders stock model is 156 cubic inches, the displacement of these two cars, which have a bore and stroke of 4 and 4½ inches, respectively, is 226.2 cubic inches, just 45 per cent. greater than the displacement of the pistons of the stock car. Although the machines are entered in a non-stock car event, the contest board believes that strictly speaking, the cars cannot be construed as Flanders models.

The course covers a circuit of 8.417 miles, and, always fast, it has been so well groomed for the forthcoming occasion, that prophecy of the speed which is likely to be attained is neither safe nor easy. It is the same course on which last year Harvey Herrick, in a National car, made the world's record average of 74.628 miles an hour, circuiting the track 24 times and covering 202.008 miles in 162:24.60, and if anyone can better that pace, he surely will have to "go some," and a little more. The entries for the three events which make up the program for Saturday are:

Class C—Non-stock cars, piston displacement from 231 to 300 cubic inches; distance 151.506 miles; 18 laps:

Louis Disbrow	Case
Ralph DePalma	Mercer
H. A. Shain	Schacht
Joseph Nikrent	Case
Earle DeVore	Buick
R. Jeffkins	Mercer
Frank Siefert	Midland

Class C—Non-stock cars, piston displacement from 161 to 230 cubic inches; distance 101.004 miles; 12 laps:

H. C. Krause	Reo
Louis Nikrent	Buick
A. J. Charles	Ford
Victor Roschen	Ford
Robert Evans	Flanders
J. Tower	Flanders
George Joermann	Maxwell

Class D—Free-for-all; distance 303.012 miles; 35 laps:

Bert Dingley	Simplex
D. Bruce-Brown	Benz
Berna Oldfield	Fiat
Theodore Tetzlaff	Fiat
Caleb Bragg	Fiat
Ralph DePalma	Mercer
Louis Disbrow	Case
David Lewis	Stutz
Earle Cooper	Stutz

Jackson in Reo Wins at Fresno.

Consistent driving enabled Earl Jackson, at the wheel of a Reo, to outstrip the eight other contestants in the Fresno (Cal.) road race, which was conducted on April 21st by the Fresno Republican, and he crossed the tape at the end of the home stretch after having made an average speed of 49.59 miles an hour. The race, which was called a 200-mile road event, but which really figures out at only 197.4 miles, was run over a course of 14.1 miles and replete with sharp bends and bad places, so that the time, 3 hours 49 minutes, in which Jackson completed the 14 laps, is good going, considering that several stops were made necessary by a leak in the radiator. Second honors went to Thomas McKelvey in an Overland car; his elapsed time was 4:03.16, or at a rate of 48.68 miles an hour. Bruce Arent, in an Elmore, was the only other contestant to finish, his elapsed time being 4:30:53, 43.85 miles per hour.

The Buick machine, driven by Dentha Sulprizio, threw a tire while rounding one of the bends at a high rate of speed. The car turned turtle and the driver and his mechanician were thrown out and more or less painfully injured. Both were removed to the hospital, where it was found that their hurts were not of a serious nature.

For the "First Farmers' Automobile Tour."

In order to attract attention to itself, Farm and Ranch, a Texas agricultural publication, is promoting what is styled the "first farmers' automobile tour," which apparently will take the form of an endurance contest. It will occur during August next, and will include the principal cities in the State of Texas.

MIX ECONOMY AND "GUESSABILITY"

Philadelphians Finally Give Real Purpose to Their Annual Event—Jones Averages 22 Miles per Gallon.

Roadability contests, which more truly are "guessability" contests, and which originated in Philadelphia, were given a really useful and interesting turn on Saturday last, 27th ult., when the fifth annual guessability stunt of the Quaker City Motor Club occurred.

The interest and the usefulness were contributed by a fuel economy test which was made part of the contest proper, and despite unfavorable weather conditions, the run served to enable W. L. W. Jones, who piloted an American underslung car to achieve the impressive record of 61.3 miles with a consumption of only 2 gallons and 28 ounces of fuel, which figures out 22.07 miles to the gallon of gasolene. The car which Jones drove weighed 3,310 pounds and was equipped with a Rayfield carburetter, model 34. The car scored 9.51 points for general efficiency out of a possible 10, while those next in line, a Lenox, by William Fowler, and a Columbia, by H. O. Krause, scored 6.62 points and 6.53 points, respectively, their respective mileages from a gallon of gasolene being 13 and 13.38.

Of the 39 machines which left the Quaker City and splashed their way through the numerous water holes and mud puddles toward Atlantic City, but nine were entered in the economy contest. The mileage covered per gallon of gasolene for each of the entrants as shown by the official records is:

American, W. L. W. Jones	22.07
Lenox, William Fowler	13.00
Columbia, H. O. Krause	13.38
American, Ralph D. Earle	9.94
Flanders, H. DeGrout	18.55
Moon, E. A. Edwards	11.48
Michigan, T. R. H. DeAuelta	12.33
American, Nelson Shaw	13.33
Krit, Albert Rich	14.71

Unlike the method of determining the official time for the guessability side of the contest, which was resorted to last year, the time was this year determined by averaging the guesses of the 30 drivers who were entered in the contest, which worked out at 3 hours, 27 minutes and 15 seconds. Otto C. Fill, driving a Packard car, finished just 30 seconds later than the official time and thereby won the first prize. Second honors went to Charles J. Swain, whose Winton machine finished the run in 3:29.03, or 1 minutes and 48 seconds over the official time.

The prize for the first woman driver to finish in the sociability contest went to Mrs. W. Walter Harper, who drove a Case car. The route was from Philadelphia to Atlantic City. The cars were parked over night on one of the piers.

BARS ONLY THE BOY CHAUFFEURS

New York's Attorney-General Interprets Reciprocity As It Relates to New Jerseymen—His Opinion In Full.

While New Jersey and Pennsylvania have managed to become embroiled over the rights of manufacturers' and other trade cars to enjoy the fruits of New Jersey's recently enacted reciprocity law, New York and New Jersey are at peace, and unless someone in New Jersey is disposed to espouse the cause of boy chauffeurs it is not likely that the relations between the two neighboring States will be unpleasantly affected.

The opinion of Attorney General Carmody, of New York, which was sought by interested New Jerseymen, effectually to remove all chance for friction unless, as stated, his ruling that as New York requires that chauffeurs shall be at least eighteen years of age, the sixteen-year-old chauffeurs who are licensed by New Jersey are not eligible to operate a car in New York, shall develop into a cause for "war," which state of affairs is extremely unlikely to come to pass.

Attorney General Carmody's opinion in full is as follows:

"First—As to the rights of motor vehicles owned by residents of New Jersey and registered under the laws of that state:

"Section 285 of our Highway Law, contained in the article relating to motor vehicles, provides as follows: 'The provisions of the foregoing sections relative to registration and display of registration numbers shall not apply to a motor vehicle owned by a non-resident of this state, other than a foreign corporation doing business in this state, provided that the owner thereof shall have complied with the provisions of the law of the foreign country, state, territory or federal district of his residence relative to registration of motor vehicles and the display of registration numbers thereon, and shall conspicuously display his registration numbers as required thereby. The provisions of this section, however, shall be operative as to the motor vehicle owned by a non-resident of this state only to the extent that under the laws of the foreign country, state, territory or federal district of his residence like exemptions and privileges are granted to motor vehicles duly registered under the laws of and owned by residents of this state.'

"From this provision it will be seen that a motor vehicle, owned by a non-resident, is exempt from registration here only to the extent that, under the laws of such state where it is registered, exemptions and privileges are granted to motor vehicles registered under the laws of this State.

"Under an act of the Legislature of New Jersey, approved April 2d, 1912, new provisions of law were adopted fixing the status of persons not residing in that state in regard to the registration and operation of motor vehicles. Section 7 of this law provided substantially that a motor vehicle belonging to a person, who was a non-resident of that State and who had registered the same and complied with the laws of the State in which he resided with respect to the registration of motor vehicles and a display of registered numbers, might be driven in the State of New Jersey for not to exceed a period of fifteen days in any calendar year. This is the extent to which, under the laws of New Jersey, exemptions and privileges are granted to motor vehicles registered under the laws of this State, and under the reciprocity section quoted similar privileges should be extended to motor vehicles owned by residents of New Jersey and there registered, and the same may properly be operated in this state for a period not to exceed fifteen days in any calendar year without registration here.

"Second—As to the rights of chauffeurs residing in New Jersey and registered under the laws of that State:

"In subdivision 4 of section 289 of the Highway Law is is provided that 'a non-resident chauffeur, who has registered under provisions of law of the foreign country, state, territory or federal district of his residence substantially equivalent to the provisions of this section, shall be exempt from license under this section; and provided, further, he shall wear the badge assigned to him in the foreign country, state, territory or federal district of his residence in the manner provided for in this section.'

"Although the phraseology of the statutes of the two States is divergent, I think that the requirements as to registration of chauffeurs are substantially equivalent. The New York statute provides that "the applicant shall pass such examination as to his qualifications as the Secretary of State shall require." (Highway Law, section 289, subdivision 1). The New Jersey statute provides that no person shall "be licensed to drive automobiles until such person shall have passed a satisfactory examination as to his ability as an operator." (Law of 1906, chapter 113, section 17).

"Although the New York statute permits the Secretary of State to prescribe the examinations, its purpose is to test the ability of the applicant as an operator of an automobile, and the intent of the two statutes is evidently the same in this regard.

"There is, however, a divergence between the laws of the two States in regard to the age limit of licensed chauffeurs, the limit in New York being eighteen years and the limit in New Jersey being sixteen years, as specified in the sections of the respective laws referred to. In this respect there is a marked difference, and I think that under a fair interpretation of subdivision 4, a chauffeur registered in New Jersey, if over the age of eighteen years, should be permitted to ply that vocation in the State of New York, but not if he is under the age specified by the New York law."

A. A. A. AND FEDERAL REGISTRATION

National Organization Alters Attitude and Grows Lukewarm—Congress's Maltreatment of Its Bill One Reason.

Several days since it became known that at the meeting of the executive committee of the American Automobile Association in Buffalo last week, a resolution was adopted which makes appear that the organization has executed a flip-flop in respect to federal registration, despite the fact that for several years it has been instrumental in introducing a bill into congress designed to attain that end.

The resolution recites that "in the opinion of the members of the A. A. A. executive committee a federal registration act is not only unnecessary at the present time, but against the interests of automobilists of the different states," and "that the imposition of an additional tax for federal registration would be unfair and unreasonable discrimination against users of automobiles, and that the passage of such a law would be most unjust." The resolution was framed by a committee composed of H. L. Vail, of Ohio, chairman; C. M. Robinson, of Connecticut, and John Wilson, of Pennsylvania. Ohio, incidentally, is one of the few states which persistently has opposed federal registration.

Officials of the A. A. A. are disposed to "fence" when their apparent about-face is questioned, but according to one of those high in authority who was present at the Buffalo meeting, the resolution was influenced somewhat by the passage of New Jersey's reciprocity bill and more largely by the fact that the A. A. A. federal registration bill has been so maltreated by congress that its fathers have difficulty in recognizing it. Congressmen Peters and Volstead, who took the bill to themselves, succeeded in having it so amended that instead of being optional, federal registration is made compulsory and drastic penalties, undreamed of by the A. A. A., have been interjected into the bill. The Peters and Volstead measures are now considered so undesirable that they no longer can claim the support of motorists. The A. A. A. resolution was framed and adopted as the result of a discussion of those two bills.

Texas Association Re-elects Baker.

George W. Baker, of Dallas, was chosen to succeed himself as president of the Texas Automobile Association, at the annual meeting of that organization, which was held on the 20th ult., at Waco. The thre vice-presidential chairs were filled by Dr. F. J. Fielding, of San Antonio; Captain J. W. Munn, of Galveston, and G. W. Hawkins, of Houston, respectively; C. H. Verschoyle, of Dallas, was elected secretary-treasurer. San Antonio was chosen as the place for the next annual meeting.

LAMPS AND AUTOMATIC LIGHTING SYSTEMS

Investigations of Leonard Kebler That Indicate the Importance of Providing Reflectors That Correspond to the Size of Lamps in Use—His Views of Dynamo Output and Speed, Method of Drive, Battery Requirements and Wiring.

While the various units that go to make up a complete motor car electric lighting system have been discussed separately and in detail on many occasions, it is not often that the system as a whole has been taken up with particular reference to the harmonious proportioning of the various components. This, however, was done by Leonard Kebler, president of the Ward Leonard Electric Co., of Bronxville, N. Y., in a paper, entitled "What the Automatic Dynamo Lighting System Should Do," read at the April meeting of the Metropolitan section of the Society of Automobile Engineers. One of the points brought out by Kebler is that the storage battery used in connection with an automatic dynamo lighting system can be called upon to do, without damage to itself, considerably more work than could be expected of it if standing on a bench, for the simple reason that the constant vibration of the car dislodges gas bubbles, and the cooling effect of the rush of air also is beneficial. Another point emphasized is that electric lamp reflectors should be proportioned to the bulbs they are to use, as little is gained by using a powerful lamp in a reflector designed for one of low candlepower.

Kebler's paper is as follows:

"In determining the necessary qualifications for a dynamo lighting system for any particular use, the following points immediately become of importance.

"(1) The lamps to be used.

"(2) The dynamo output needed.

"(3) The dynamo speed and the method of driving the dynamo.

"(4) The proper size storage battery to be used with the dynamo selected.

"(5) The type of wiring.

"The most important of these is the first, that is, 'What lamps to use.' There are only three size bulbs now in general use for headlight work, these being, respectively, 16, 21 and 25 candle power. For small motor cars which travel at comparatively slow speed, and where the owners would be satisfied with light that, while better than acetylene lights usually supplied with these small cars, is still not the most powerful, and where he will not be liable to compare his lights with those of friends who have higher power to the detriment of the 16 candle power lamps, 16 candle power is undoubtedly ample. On the higher powered cars the 21 candle power bulbs are almost in universal use today. These will give ample light for driving up to a speed of say 40 miles an hour at night, illuminating the road far enough ahead so that any object may be observed in time to stop almost as well as in the day light, and in fact gives all the light that is needed. Such lamps, when used with a shallow parabolic reflector, will light a road 50 feet wide for the full width of the road from the front of the car to a point over a quarter mile away. A deep parabola of the same focus will light the road even further, but will not give as much light at the sides, close to the car.

"Where extremely high-powered cars are used, running at very high speed, and where very large reflectors can be used, 25 candle power bulbs are sometimes used.

"It must be realized that with small reflectors, built to take a 16 candle power bulb, the insertion of a 21 candle power bulb will not give the proportionate larger amount of light on the road that 21 is to 16, and similarly a 25 candle power bulb in a reflector built for 21 candle power will not give sufficient additional light to warrant its use.

"With a commercial reflector having the greatest diameter of 8 inches, a 16 candle power bulb is about all that can be economically focused. With one of 10 inches diameter a 21 candle power bulb should be used, and there is little use in using a bulb larger than 21 candle power unless you have a 12-inch reflector, which is very seldom seen, on account of the large size.

"The side lamps and rear lamps are signal lamps only, and for these bulbs of small candle power can be used. Four candle power or two candle power bulbs are adequate, and it is customary to use a 4 candle power side lights, and 2 candle power rear lights. The amount of current taken by these side and rear lights is so small that there is no objection to using 4 candle power bulbs for all three, or 2 candle power for all three, but the desirability to have a brilliant light at the side, for appearance, has led to the use of 4 candle power bulbs. Frosting these bulbs in the side lights gives a very pleasing appearance, and I think will be very largely adopted in the near future. In order to make sure that we have ample overload capacity to take care of the many short loads made by the horn, speedometer light, etc., the dynamo should be capable of delivering to the storage battery slightly more amperes than is required by the lamp load. For this reason an ampere output of 10 amperes of the dynamo has been almost universally accepted as the proper amount when such a lighting equipment is used. This will keep the storage battery always up to the best efficiency, and at the same time it is small enough, so that the storage battery will not have to have too large plates in order to run without undue deterioration.

"The dynamo should be so geared to the car as to give its full output at from 15 to 18 miles an hour and any speed above this.

"At a speed lower than 15 or 18 miles an hour, the car will not be driven for more than a very few miles with all the lights lighted, and the reserve capacity of the storage battery will more than make up for this short time. Of course, when the car is being driven in the city, where the headlights are not being used, it often runs slower than this speed, but at these lower speeds the dynamo is generating a proportionately smaller amount and will give ample current to take care of the two sides and the rear lamp, which takes only a total of about 2.3 amperes.

"A shunt-wound dynamo which will deliver 10 amperes at say 15 miles an hour, will deliver 2.3 amperes at 8 or 9 miles an hour, so that whenever the car is running it will supply ample current for the side and rear lamps.

"In dynamos of any one type, the size, weight and cost is determined by the ampere capacity and the speed at which this number of amperes can be put into a 3-cell lead battery.

"The cost of a dynamo which will deliver say 6 volts and 10 amperes at 1,500 revolutions per minute is 30 per cent. less than one which gives the same output at 1,000 revolutions per minute, and it is less than half the cost, and of about half the weight of one designed for the same output at 500 revolutions per minute.

"A shunt-wound dynamo designed to put 10 amperes into a 3-cell battery at about 1,000 revolutions, weighs approximately 21 pounds, and can be made approximately 8 inches long by 5⅝ inches high by 4¾ inches wide. If we reduce this speed to 500 revolutions the weight becomes approximately 33 pounds and the dimensions approximately 9¼ by 7½ by 4¾ inches.

"This 1,000-revolution dynamo should be run at about twice engine speed for the best results, and the 500-revolution dynamo should be run at engine speed for the best results. The question immediately comes up as a matter of judgment, whether there is sufficient advantage in running at the slower speed, to make up for the added weight and the added cost.

Digitized by Google

"It will be found in general that where a shaft is provided on the engine to which the dynamo can be coupled, and this shaft runs at engine speed, the added weight and cost of the engine speed dynamo is warranted, because it eliminates the cost and complication of sprockets and chain for driving the dynamo. But where such a shaft would have to be put specially in the engine, and driven by gears, or when some shaft already projecting runs at engine speed, but is not so located that the dynamo could be directly coupled to it, and consequently either gears or sprockets and chain have to be used, there is little question but that a dynamo delivering its full output at 1,000 revolutions per minute and running at about twice engine speed, is the happy mean in the weight, cost and size. A dynamo which will put 10 amperes into a 3-cell battery at 1,000 revolutions, driven at twice engine speed on a car with 36-inch wheels, geared 3½ to 1 on the back axle, will start to charge the battery at from 6 to 7 miles an hour, and will give enough current to supply all the lamps, that is, about 10 amperes, at 15 miles per hour.

"The same dynamo on a car geared 3 to 1 with 36-inch wheels, starts to charge the battery at 9 miles per hour, and will deliver enough current to take care of all the lamps at 18 miles per hour. Such a dynamo I believe to be the ideal one, where there is no provision made for driving directly at engine speed.

"A machine running at higher speed than this has not sufficient advantage in less weight, and cost, to warrant the higher speed of the chain and the higher speed in revolutions per minute of the armature, and to warrant the additional wear on the bearings, and additional chance for noise. At the same time the use of a dynamo at less than twice engine speed to get a reduction in chain speed and wear on the bearings, has not sufficient advantage to warrant the use of a larger, heavier dynamo, running at say engine speed and driven by chain, or gears.

"On a dynamo driven by ⅜-inch pitch silent chain at twice engine speed, sprockets of 30 and 15 teeth would be used. At 45 miles per hour this chain would run at 1,500 lineal feet per minute and at 60 miles per hour at 2,000 feet per minute. This is not an execessive speed, but if a dynamo giving its output at 1,500 revolutions per minute were used running at three times engine speed, we would use 45 and 15-tooth sprockets and the chain speed becomes 2,250 feet per minute at 45 miles per hour and 3,000 at 60 miles per hour, which is too high for efficiency or long life. We may, therefore, decide not to run our dynamo at over two times engine speed.

"On the other hand, where it is possible to drive at engine speed through an Oldham coupling, the ideal case is undoubtedly reached, and in this case the additional weight and cost of the dynamo is warranted, as we save the additional cost of sprockets and chain and eliminate the necessity of oiling these, etc.

"A very useful method of driving the dynamo is to extend the pump shaft through the pump, leaving an extension to be directly coupled by means of an Oldham coupling.

"In other cases it is possible to have the armature shaft of the dynamo extend through both ends and drive from the timing gears through the dynamo armature to the magneto, having the magneto and the dynamo lined up in tandem. In each of these cases a dynamo running at engine speed is used for the 4-cylinder car, and 1½ times engine speed for a 6-cylinder machine.

"When neither of these methods is possible, and it becomes necessary to drive the dynamo by gears or silent chain, we will then use the higher speed machine, running at about twice engine speed, and this can be driven in a number of different ways.

"Where the pump is driven separately from the magneto, it may be driven at twice engine sped and the dynamo can be run directly from the pump shaft through an Oldham coupling.

"Where a shaft running at twice engine speed can be installed projecting from the timing gear case ,or from the gear box, it can be driven by gears or chain running in oil, and then the dynamo can be directly coupled to the shaft. This gives a noiseless and almost wearless drive.

"A sprocket on the pump shaft or magneto shaft driving a sprocket on the dynamo by silent chain at twice engine speed, is quiet, efficient and satisfactory. It is, of course, better if the chain can be enclosed and run in oil.

"Having determined all the necessary features of the dynamo regarding its output, speed and method of drive, we turn to the storage battery. The first thing to determine is the proper size storage battery to use with the dynamo selected. A proper storage battery must fulfil two conditions. (a) If the car owner runs entirely in the day time the battery must have sufficient square inches of plate surface to be charged whenever the engine is running at the maximum dynamo amperes without injury to the battery. (b) If the car is standing still with all lights lighted, the battery capacity should be sufficient to keep all the lights burning for 6 hours, and when only the side and rear lights are on, it should be capable of keeping these lighted for say two nights, or 24 hours.

"Considering 'A,' experiment shows that a battery having 160 square inches of positive plate surface and 200 square inches of negative surface, will not be injured by use with a dynamo giving 10 amperes output on an engine. Such a battery would undoubtedly be ruined if 10 amperes were put into it continually on the test bench, but the conditions in motor car service are so different as to require some comment.

"There are two things that cause rapid deterioration of storage batteries when they are charged continuously at high rate. The first is that the heating of the battery due to continuous charging, softens the plates so they become readily disintegrated. The second is that large bubbles of gas form on the negative plates, and when these bubbles break away from the plates, they take particles of the active material, especially when this has become softened, due to heating.

"On motor car work, in the first place, it is very seldom that a battery is charged continuously at the maximum rate for more than two hours at a time. There are always stretches of a few minutes when the engine is slowed down, so that the dynamo does not deliver its full output, or when the engine is stopped entirely, and the battery has a chance to cool off. As a result the service is not at all analogous to tests made on a test bench where the current is put into the battery continuously. On a test bench the battery would get hot, but on a car it will not.

"In fact in a battery with the plate surface already decided, there is little or no heating in ordinary service, and no excessive heating in the most severe service.

"In the second place the large air bubbles do not have a chance to form on motor car batteries, due to the jarring and jolting that a motor car gets in going over the road. Before the bubbles have time to become large enough for them to take off a serious amount of active material when they break away, they are jolted loose and do not injure the plates to any material degree. As a result it will be found that storage batteries can be run at almost double the charging rate without undue deterioration on a motor car, than they can when standing still on a bench.

"The mechanical agitator now often used for large stationary batteries to keep bubbles from forming, is replaced by the jolting of a motor car, and the various methods of cooling often adopted for large stationary plants, is taken care of in this case by the occasional slowing down of the engine and occasional stopping of the engine.

"A battery on a motor car is run under ideal conditions, because it is being constantly charged and discharged under ideal conditions as regards agitation and coolness. A battery having the plate surface mentioned above will light all the lamps, that is, discharge at a 9½ to 10 ampere rate for about 3¼ hours, and will light the side and rear lamps for 24 hours. Such a battery does not light all the lamps long enough, so that if batteries of this size are used there should be two of them, or a larger capacity battery, having at least 80 ampere hour capacity at a 10 hour rate, can be used. Any battery made by a reputable maker and having 80 ampere hour capacity at a 10 hour discharge rate, will fulfil all requirements. This latter battery will fulfil all the specifications and has ample plate surface, ample capacity to run all lamps for at least 6 hours, and the side and rear lamps for 24 hours."

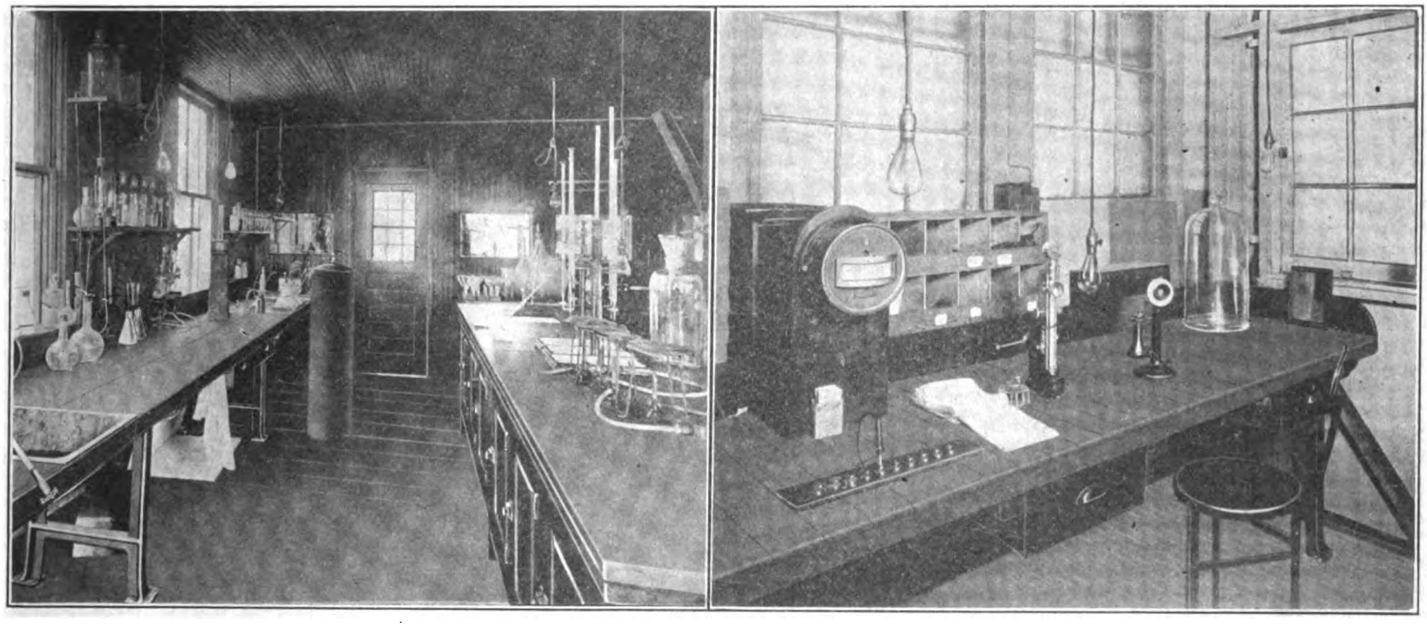
CHEMISTRY AND HEAT TREATMENT FOR MOTOR CARS



Manufacturing Processes That Have Been Improved and Results, Once Problematic, Made Certain by Scientific Manufacturing Methods—Centralized Control of Scattered Apparatus—Ingenious Testing Apparatus for Ascertaining Results of Various Processes.

Among the various processes that are carried out in the transforamtion of raw material into finished motor cars, there is none more shrouded in mystery than the heat treatment of steel, a process by which the very highest qualities of steel are brought out, and one which requires the utmost care for its successful termination. While the term heat treatment in its broader sense may be taken to include the familiar and ancient process of hardening and tempering tool steels, in its commonly accepted meaning it includes only the more recently developed methods of treating steels which are alloys of iron and small quantities of various other substances, such as nickel, vanadium, chromium, titanium and tungsten. Heat treatment consists, as the term indicates, of heating the steel in special and carefully regulated furnaces, the heating being followed by a cooling process which is controlled no less carefully than the heating, being in some cases very slow and in other cases rapid, as when the hot metal is "quenched" or immersed in a bath of water, oil or other liquid.

In heat treatment the whole process is governed by the characteristic behavior of the different components of the alloys under the influence of heat. Until quite recently it has been a matter of the utmost difficulty to obtain anything like uniform results from heat treatment of a number of pieces, or, for that matter, to obtain results approximating those sought for in one or two. There are very good reasons for this. The degree of heat required to bring about the best results differs not only with the substance with which the iron is alloyed, but with the proportions of the components; a little too much heat, or not quite enough, or a rapid cooling instead of a slow one, or vice versa, any one of these things may make the heat treatment of no avail, and the steel may be left in worse condition than before the treatment was attempted.

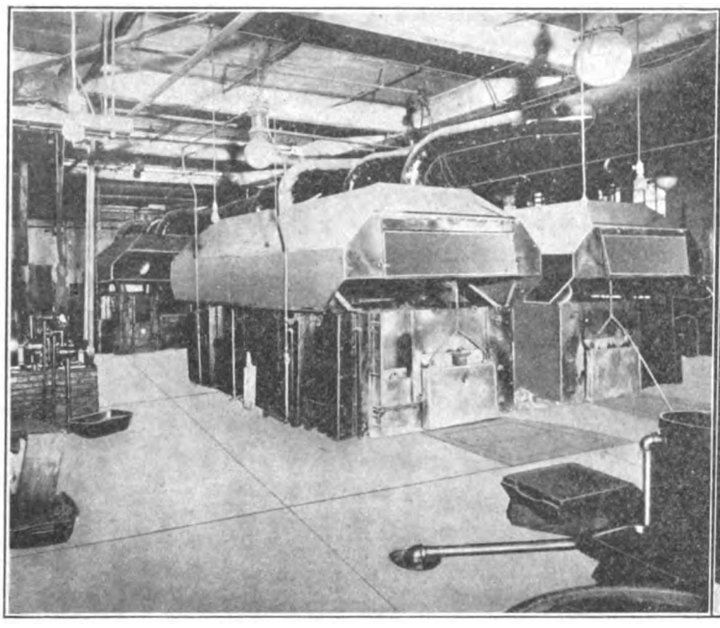
Controlling the alloys in the first place, and accurately regulating the heat in the second place, as well as learning just how the various mixtures were affected by different treatments have taken years of the hardest kind of work and study. Now, however, the chemical properties of the various substances are quite thoroughly understood, metallurgists are familiar with their behavior under heat and, last but by no means least, methods of heating and of indicating and controlling heat have been so vastly improved that large quantities of steel can be treated with certainty as to results. The furnaces used for the heating processes are fired with gas—natural or manufactured, according to the local conditions—or with oil, sprayed and mixed with air. The use of such fuels makes it possible to regulate the heat to a nicety by the mere manipulating of valves, and to maintain the desired heat for any required length of time. In furnaces burning coal or other solid fuel any such regulation as that required for the heat treatment of steel would be manifestly impossible.

Check is kept on the temperature inside the furnace by means of a pyrometer, which is in effect a thermometer built for extremely high temperatures. It differs from the ordinary thermometer, however, very widely. Instead of depending upon the expansion of a liquid under heat the unequal expansion of two dissimilar metals is turned to account, and in one type advantage is taken of the fact that an electric current is generated when two dissimilar metals are heated while in contact with each other. Electrical connection is made from the "couple," which is located within the furnace, to a very sensitive volt-meter, each side of the meter being wired to one member of the couple. Instead of being graduated in volts or fractions of volts, however, the meter is graduated to read in degrees. The hotter the couple becomes the more current is generated and the meter needle indicates accordingly. One of the great advantages of this system is that the temperature can be watched at any reasonable distance from the furnace, it being necessary only to carry the connecting wires to the meter. A whole battery of furnaces can be checked up from a single point

GENERAL VIEW OF HYATT LABORATORY

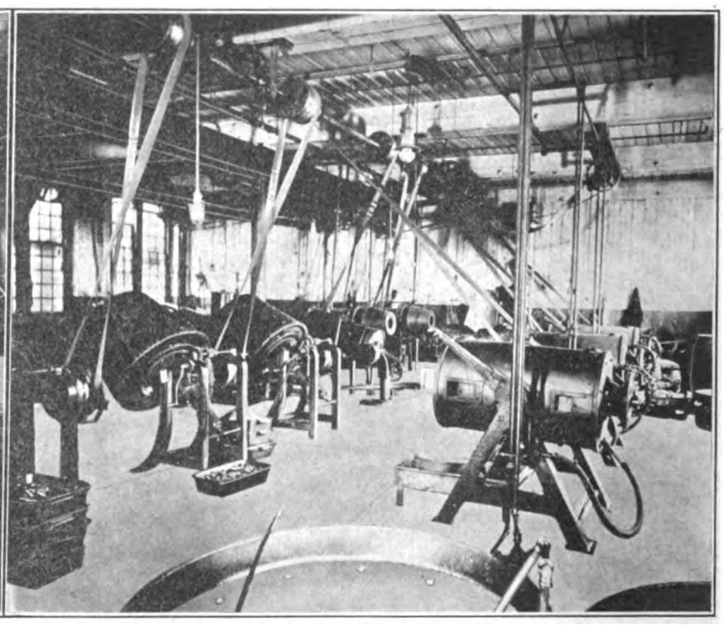
CORNER OF HEAT CONTROL STATION

Digitized by Google



by installing one meter and a switchboard through which any furnace can be "plugged in" on the meter. The steadiness of the heat in a gas or oil furnace makes it unnecessary to do more than take occasional readings, so that this arrangement is all that is necessary. A furnace of this type also permits the simultaneous heating of a large number of pieces to the same temperature, so that in a manufacturing plant where production is in quantity this process is invaluable.

While extreme hardness of steel is not always the object sought in heat treatment, it is the object in some cases, and in all cases the various degrees of hardness of steel are indications or accompaniments of other conditions. For instance, a steel that is extremely hard will be extremely brittle, while one that is of extreme softness will bend very easily. Between these extremes will be found conditions which may be said to be the result of compromises. Spring steel, for instance, is so hard as to resist bending to the extent that it will not take a permanent "set" or change of form when bent, but will return to its original shape if the bending effort has not been carried beyond the elastic limit of the material. If the steel is too hard it will not bend sufficiently without breaking; and on the other hand, if it is too soft it will take a permanent "set" because it is deficient in the springy quality that comes from hardness. There is a certain degree of hardness that is the best for a given purpose, and while in a given instance it might perhaps be desirable to have the metal slightly harder, it might be that more hardness would result in brittleness, so that a compromise is necessary. But here is where the different characteristics of different alloys find much of their value. A steel that might be quite stiff enough for a certain duty when brought to a certain degree of hardness might be just brittle enough to snap under an execessive stress, while another alloy might attain the same degree of stiffness while remaining considerably softer, so that in case of abnormal loads or shocks it would merely bend, permitting the re-shaping of the part.



In order to determine the physical characteristics of various steels all kinds of tests are made with instruments and machines that differ according to the tests they are required to make.

Tensile strength is accertained by a machine which grips both ends of a bar and by main force pulls it in two, the number of pounds required to do this being indicated at the same time. Resistance to vibration and bending stresses is shown by a machine which holds a bar of steel fixed at one end while the other end is moved back and forth until the bar breaks, the indicator registering the number of vibrations or bends required to cause fracture. Transverse strength is ascertained by supporting a bar at both ends and applying pressure at the middle, the amount of pressure required to bend the bar or to break it, as the case may be, being registered. Resistance to compression is tested by crushing samples in a machine that crushes and at the same time indicates the pressure exerted. Other devices are used to test elasticity, ability to withstand short bends, torsional or twisting strains, shearing or cutting strains and so on. As might be imagined, the problem of accurately testing and indicating the degrees of hardness of steels required no little ingenuity to solve, but solved it was. Among the instruments most used for this purpose—which are called scleroscopes—one is arranged to press a steel ball of extreme hardness into the sample under test, the number of pounds required to force the ball to a given depth being the standard, or else the depth to which the ball can be sunk with a constant pressure. In the latter case the depth of the depression made by the ball is the standard, and is accurately measured by a special instrument with an indicating dial marked off with an arbitrary scale. Another type of scleroscope drops a steel ball on the surface of the sample and the distance of the rebound of the ball is the measure of hardness of the metal, the ball rebounding higher from a hard surface than from a soft one.

Physical tests are useful as indications of physical characteristics, but alone they do not furnish the data needed by the metallurgist in determining how he shall proceed in the matter of heat treatment, for this is a matter of chemistry. Therefore chemical analyses are made of samples taken from the stock and the treatment adopted is based on the results obtained in the chemical laboratory; the physical tests made of the material after treatment are compared with tests made before treatment, the difference in results indicating the efficacy of the processes. Such analyses and physical tests are of the greatest importance—in fact, it may be said that they are absolutely necessary—in manufacturing establishments where large quantities of steel parts are turned out, all parts of a kind requiring to be uniform in every respect. In the manufacture of roller bearings, for instance, it would be a fatal error to permit any variation in the hardness of the rollers, for it would mean that in service the wear would be unequal and the antifriction qualities of the bearings would be seriously impaired and their useful life shortened. Of the very large manufacturers of such bearings the Hyatt Roller Bearing Co. is conspicuous for its unusually thorough methods of dealing with the treatment of steel from the analytical lab-

HYATT'S HEAT TREATING FURNACE ROOM

BATTERY OF CASE-HARDENING OVENS

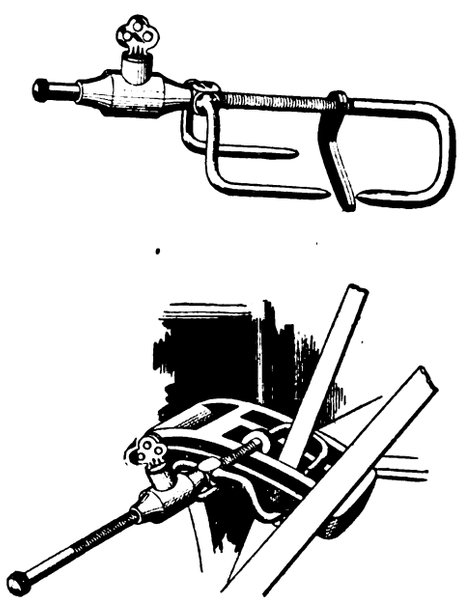
oratory tests right through to the final gauging and inspecting of finished parts. It is fairly obvious that where vast numbers of parts are turned out anything that will ensure uniformity means economy in the long run, almost regardless of the cost of providing such safeguards. Therefore it is quite in the natural order of things that the Hyatt factory at Newark, N. J., should be equipped with the most approved apparatus. The accompanying illustrations serve to indicate the elaborateness of the installations and the clean, unencumbered appearance of the factory.

The first step, when raw material reaches the factory, is to make a chemical analysis of samples from each shipment received, the results being systematically recorded. A sufficient number of samples is analyzed to eliminate all doubt as to the uniformity of the quality of the steel throughout each shipment and to furnish a sound basis upon which to calculate the subsequent heat treatment. The machining process follows, in which the stock is formed, just sufficient surplus material being left to allow for the final finishing by grinding. The Hyatt bearings having flexible rollers formed of spirals of steel, it is particularly important that there should be in the material used the most effective combination of tensile strength and elasticity, together with sufficient surface hardness to resist wear. The desired results are obtained by using steel having particularly suitable qualities and heating it to a predetermined temperature, quenching it in a liquid, which results in great hardness, and finally re-heating, which considerably tempers the glass-like hardness and at the same time increases the toughness of the steel. To indicate the remarkable efficacy of heat treatment of steel a comparison of figures may be made, the three qualities mentioned being those particularly necessary in the rollers. The tensile strength of one particular sample before heat treatment was 116,300 pounds per square inch, that being the force required to tear apart a bar having a cross sectional area of one square inch. After treatment it needed 216,800 pounds, an increase of 100,500 pounds. The elastic limit was raised from 95,300 pounds to 196,000 pounds, more than doubling the figures. Before hardening the scleroscope scale indicated 41, and after hardening. 60. The rollers are of uniform temper throughout.



For the races which form the inner and outer surfaces upon which the rollers travel a different material is required and a different mode of treatment. Flexibility is not required—in fact, it is most undesirable—but a hard, wear-resisting working surface is essential. Therefore a process is adopted which is known as carbonizing, the races being packed with granulated bone and other substances in furnaces and subjected to a carefully regulated heat for a length of time which varies with the size of the parts and the depth of the hard "case" required. For example, a piece ⅛ of an inch thick and 1⅛ inches in diameter requires "soaking," as it is called, for nine hours in order to permit carbon to penetrate to a depth of 3/64 of an inch. This carbonized stratum is capable of being hardened, and is hardened, while the core remains comparatively soft and tough, the combination producing a race that is at once rigid and not liable to fracture.

All the furnaces used in these processes are equipped with Le Chatelier pyrometers, electrically connected with a central control station consisting of a switchboard and an indicating instrument, as shown in the illustration. Each furnace is cut into the indicator circuit at stated periods and the reading recorded and, if necessary, the gas or oil feeds adjusted to keep the temperature within the prescribed limits. Samples from each "heat" are fractured and examined by the metallurgist in charge through a microscope and tested as to physical qualities in an Olsen testing machine. Incidentally, races are required to be considerably harder on their working surfaces than the rolls, testing to 80 on the scleroscope, as against 60 for the rolls.

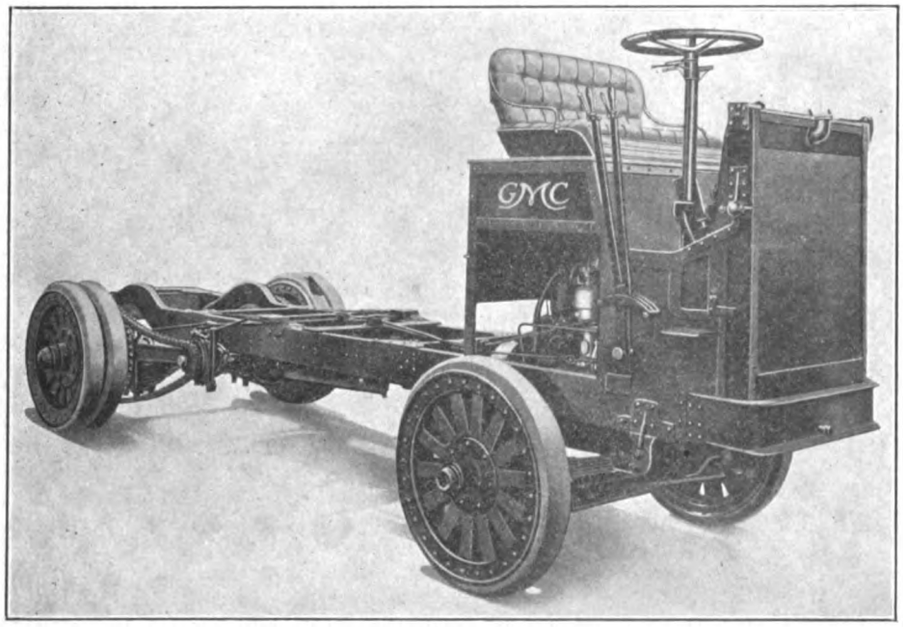
While what has been said gives an idea of the elaborateness required for the proper handling of steels in a large manufacturing establishment, it can convey no idea of the enormous amount of scientific research and experiment that has gone before. The production of each particular variety of steel has been a study in itself; so have the evolution of the heating apparatus, the development of the testing instruments and the working out of the various hardening and carbonizing formulae. Behind all this there are the years spent by the metallurgical chemists and the heads of various departments in acquiring the highly specialized knowledge required for their work. It is not difficult to understand, therefore, that any industry which is devoted to the production of steel products of a high quality is not the result of a mushroom growth, but rather is the culmination of years of hard work in many branches of science.

Moon Devises a Gear Lever Lock.

While devices designed to prevent the unauthorized use of motor cars are legion and the means of making them effective are as numerous as are the places on a car where they can be applied, there can be no gainsaying that a device which, when properly applied, absolutely prevents the shifting of the gear lever from neutral position can be relied upon to frustrate any attempt to operate the car. Such an attachment is the Moon auto lock, which just recently has been placed on the market by the Moon Specialty Sales Co., of 1223 South Olive street, San Francisco. The accompanying illustrations, which show the Moon lock separately and attached to the quadrant, reveal both the construction and the method of application quite clearly. The lock is claimed to be proof against filing, sawing and picking; two keys are furnished with each lock and no two locks can be opened with the same key. While the lock prevents the operation of the car because it makes the meshing of the gears impossible, it does not interfere in the least with the moving of the car by hand.

MOON LEVER LOCK

Dow Develops a Tire For Trucks.



Alexander Dow, of New York, who is fairly well known to the trade by reason of his connections as a consulting engineer, and also because of the rim and non-puncturable inner tube which bore his name, has made still another incursion into the realm of vehicle tires, his latest invention bearing the United States patent number 1,024,189 and the date of the 23d ult. It is a solid commercial vehicle tire that has claimed the attention of the inventor this time, however, and its construction is such as to give real promise of its possibilities. Already one well-known tire manufacturer who shortly will embark in the manufacture of the usual types of solid rubber tires has evidenced sufficient interest in the new Dow tire to go to the expense of getting out molds and manufacturing some of the tires for testing purposes with a view to producing it on a royalty basis. Incidentally, some of the tires which are to be produced in the near future will be shipped abroad to be tested by the British Dunlop company on some of the buses of the London General Omnibus Co. The object sought in the new tire is to reduce cutting and chipping away of portions of the rubber and to this end several layers of fabric are inserted in the body of the tire. In order to permit compression and a certain elongation of the rubber without fracturing the cotton fabric, however, the latter is inserted in diagonal and undulating sections in such a way that distortion in any or all of the three directions may take place without serious consequences.

BODY THAT FACILITATES LOADING

General Motors' New Design Brings Truck Platform Close to Ground—"Kick-up" Over Axle a Feature.

That the economical operation of motor trucks depends to a great extent on loading and unloading facilities is a matter of fairly common knowledge. Economy of operation depends on system and just as surely as system reduces maintenance cost by eliminating waiting time, which must be charged against the investment represented by the vehicle, so will the efficiency of the service appreciate. Consequently in the majority of cases where several trucks are operated under the same ownership considerable attention is devoted to providing suitable loading platforms to reduce the idle time of the trucks to the minimum. But whereas such methods take into consideration one end of the haul, little attention is paid to the other end, where, as a rule, the driver (and his helper if he has one) is left to his own devices, which necessarily are limited in compaarison to the facilities at the home station, to unload his vehicle. As a result, the time that may be saved at one end often is more than offset by the time that is lost at the other end.

NEW 5-TON G. M. C. CHASSIS WITH UNDERSLUNG SPRINGS

It is in appreciation of these facts that the General Motors Truck Co., Detroit, Mich., has added to its already extensive line of commercial vehicles a new type of chassis which is calculated to reduce operating costs by facilitating loading and unloading at both ends of the haul. To attain this desirable result, the manufacturers have had recourse to the simple expedient of attaching the rear springs to the under side of the axle. Though the idea expressed in the construction is not absolutely new, it has been carried a little further than is usual by forming the side members of the frame with a decided "kick up" over the axle and in this way the total distance between the road surface and the loading platform has been reduced to the point where it is just sufficient to permit of ample road clearance.

The construction of the new chassis makes them particularly suitable for use where loading platforms are not provided, as on docks, for instance, and where frequent discharges of freight at the road or street side are necessary, as less time is required and the operation of shifting the load from the comparatively low platform is less burdensome than would be the case with the ordinary truck. The actual measurement between the loading platform and the road surface, with the truck loaded to capacity, is but 24 inches; it is slightly more when the truck is light, of course, though in any case the height is considerably less than it is with ordinary construction.

The new chassis is made in two sizes, namely, 3½ and 5 tons capacity, and except for the shape of the frames and the underhung spring suspension does not differ materially in mechanical construction from the standard G. M. C. models of the same capacities. The wheelbase of both models is 138 inches and the chassis prices are $3,700 and $4,700, respectively.

Less Than 6,000 Automobiles in Spain.

According to the last official returns, there were but 5,500 motor cars registered in all of Spain, of which number 1,950 had been registered during the year 1911, indicating that the advance of the automobile is not particularly rapid in that country. During the year 1911, however, the imports of automobiles jumped from $2,225,000 to $3,425,000.

YELLOW AS A CATCH-FARE COLOR

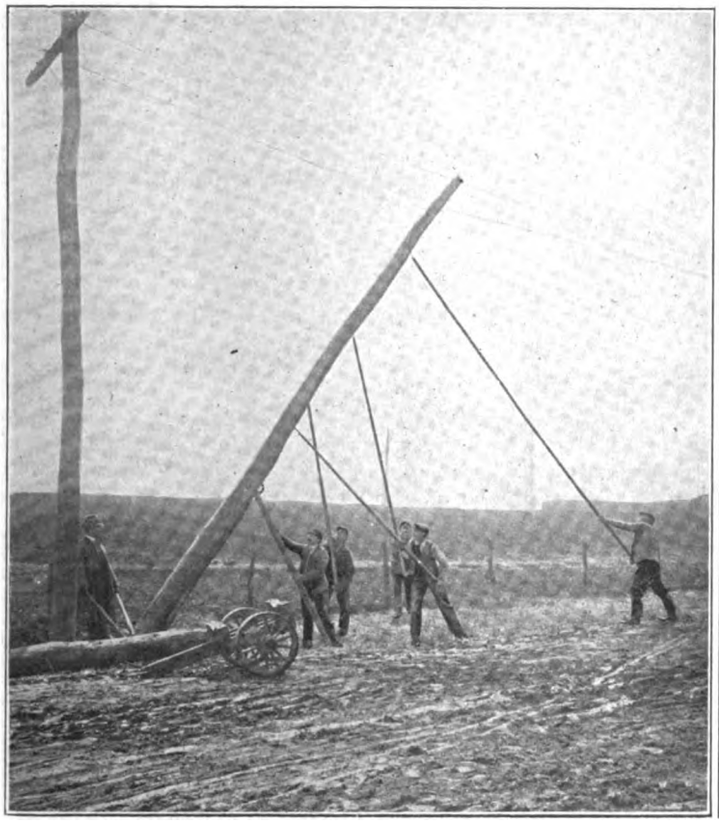
Legal Proceedings Uncover Trick of the Taxicab Trade—Big Company Forces Small Operator to Repaint Cabs.

Due to an action instituted last week by the Yellow Taxicab Co., of New York City, against Alfred Biancheri, light was thrown on one of the many unsuspected tricks of the taxicab trade. As its title suggests, the Yellow Taxicab Co. operates cabs of which yellow is the distinguishing hue. There are so many of them that Biancheri, who owns but two cabs, adopted yellow as his color and, according to the allegations in the case, he was but one of a number of small operators who did the same thing in an effort to attract business from the big company.

According to the complaint, so much confusion resulted from the similarity of colors that many patrons of the Yellow Taxicab Co. took other yellow cabs by mistake and were embarrassed when they found that their account cards were of no service.

The particular color claimed by the Yellow Taxicab Co. is described in papers as Bristol orange. It is claimed that it has become a trade asset and whether or no any cab owner has a monopoly of a particular color, Judge Erlanger, in the New York Supreme Court, granted an injunction restraining Biancheri from "maintaining, constructing, decorating, painting or offering for private or public hire taxicabs so designed, constructed, painted or decorated in imitation of the plaintiff's yellow taxicabs, or so closely designed or decorated as to be intended to defraud and lead the public and patrons of the plaintiff to patronize and hire the taxicabs of the defendant with the belief that the same are taxicabs of the plaintiff."

It is likely that similar proceedings will be instituted against several other offenders.



To Give Medals for Maxwell Miles.

In order to stimulate the interest of Maxwell owners and, incidentally, to keep a line on the performances of their cars, the Maxwell-Briscoe Motor Co. has undertaken the promotion of what will be styled the 50,000-mile Maxwell Motor Club, which will provide gold medals for all Maxwell owners who have completed, or may complete, 50,000 miles. Silver medals also will be awarded to those who reach the 25,000-mile point. It is not essential, however, that the entire distance be covered in one Maxwell car. Berry Rockwell, who is attached to the publicity department of the United States Motor Co., of New York, of which the Maxwell-Briscoe company is a part, has been designated secretary of the 50,000-mile club and will have immediate charge of the compilation of the mileage records and of the distribution of the medals.

MOTOR TRUCKS' BIG PART IN TELEPHONE SERVICE

What They Have Done to Facilitate Operations of One Prominent Company and How 48 of Them Save $72,000 a Year—Their Practicability Amply Demonstrated But Horses Not Wholly Displaced—Interesting Facts and Figures Born of Eleven Years' Experience.

OLD WAY OF ERECTING TELEPHONE POLES

MODERN WAY OF PERFORMING SAME WORK

It may seem inconceivable to the average man in the street that the replacement of horse-drawn vehicles with 48 motor trucks, 43 of them being gasolene, of which 10 are of 800 pounds capacity, and the other 5 are electric, could be directly responsible for a net annual saving in operating expense of $72,000. And yet, startling as the figure may seem, this enormous saving has been effected and still is being effected by the New York Telephone Co.—in fact and not in fancy.

System and organization are the backbone of every business of magnitude and it is doubtful if any business is run under more economical conditions than that of the truly immense New York Telephone Co.; it exhibits a nicety of adjustment and a smoothness of operation that can only be obtained with the aid of the oil of real efficiency. It requires that the latest and most up-to-date methods and machinery be employed—any paying business does, for that matter—and after all it may not be so surprising that operating costs have been so materially reduced during the past few years with the help of motor trucks.

But just as has been found in hundreds of other cases, so it has been found in the case of the New York Telephone Co.: The motor truck may not be used indiscriminately if ultimate efficiency is to be advanced. It has its sphere of usefulness and it gradually is being increased in size. But it cannot hope to compete with horse-drawn vehicles in economy of operation under certain conditions. In some cases the motor truck has completely ousted the horsed vehicle, but in other cases it has not and it is doubtful if it will for quite a long time to come.

Consequently, despite the enormous saving of some $72,000 which is effected with the help of 48 motor trucks—there still remain 5 more trucks, 14 touring cars and 97 runabouts to be accounted for, and though the total saving is not divulged it would seem $72,000 is a modest figure—the company continues to make annual outlay of some $385,000 for the hire of horsed vehicles; they are used where the employment of motor trucks would cause a deficit instead of a saving.

Such are the facts and figures as compiled by A. W. Allen, who is the superintendent of buildings and supplies for the New York Telephone Co., and they cover a period of 11 years. He tells, in the Telephone Review, which is the house organ of the company, of the first experiments which were made with motor trucks and the experience of the company from 1901 up to date, and it is seldom that a more interesting statement of operating experience makes its appearance.

"Back in 1901, when the New York Telephone Co.'s field of operation comprised Manhattan, The Bronx and Westchester, the construction department put in service the first motor vehicle owned by the company," says Allen. "This was an electric, manufactured by the Vehicle Equipment Co., of 10,000 pounds capacity, equipped with two 1¼ horsepower motors for propelling the truck, taking current from a lead battery and another motor of two horsepower taking current from the same battery for operating a 'nigger head' used for pulling cable into the subway. This was before the time of extensive aerial cable construction work, so that in the design of the pulling

Digitized by Google

device, only the conditions met with in underground work had to be considered. This truck remained in service until 1907.

"From 1905 to 1909, three more electrics were purchased; two of 2,000 pounds capacity and one of 3,000 pounds capacity. These were of the Lansden make, equipped with Edison batteries. All three of these trucks are still in the delivery service of the repair shop.

"In 1907, the construction department in New York put in service the first gas truck owned by the company. This was a Hewitt of 10,000 pounds capacity and equipped with a Higbie hoisting winch geared to the truck engine. This truck has a splendid record and is still in service.

"The developments and economies resulting from the use of the Hewitt truck in Manhattan, The Bronx and Westchester, in both underground and aerial cable work, created a demand for motor trucks throughout the company's territory which at this time included the old New York company operating in Manhattan, The Bronx and Westchester, and part of Connecticut, and the merged companies operating throughout the remainder of the State of New York, and a part of the State of New Jersey. This demand was due largely to changes in outside construction methods involving a more general use of aerial cable. The amount of this work under way and contemplated, made it apparent that a limited number of trucks equipped with power winches could be kept continually busy for a number of years. In the fall of 1910, a careful study was made to determine the number of motor trucks required in each plant division, considering only their installation where continual use and a saving in man labor would insure greatest economy. This study led us into a consideration of motor vehicles, not only for cable construction, but for all other lines of telephone development and maintenance work.

"The transportation problem of the Telephone company is made up of a number of fairly distinct elements:

"a: The transporting of heavy construction material.

"b: The use of a truck equipped with a power winch as a tool in erecting poles and placing lead covered cable in the plant.

"c: The transporting of loop gangs with their tools and equipments.

"d: The delivery of splicers' supplies.

"e: The delivery of subscribers' station apparatus.

"f: The distribution of repaired material from the shop.

"Over a period of several months, records were maintained of loads carried by horse-drawn trucks both in underground and aerial cable work (classes a and b). These records showed that the average load was about 5,000 pounds, although in a number of cases 8,000 pounds were carried, and in other cases, two trips of a horse-drawn truck were necessary where one trip of a large capacity motor truck would have proven more economical. These cases however, were infrequent enough to show that on the average a truck to meet the maximum condition would go out loaded to about half of its capacity, and the cost of maintenance, as against a truck which would more nearly meet the average condition, was so much higher as to entirely offset this saving in carrying the occasional heavy load. We, therefore, decided that a truck of 6,000 pounds capacity would best meet our requirements, and that it must be equipped with a power winch and a strongly built body of special design.

"In the study of loop work (classes c, d and e) the requirements were radically different from those met with in a consideration of construction work. The trucks would be used in the delivery of subscribers' equipment and splicers' supplies, and in the transportation of loop gangs with their tools and equipment. No winch was required in this service, and the economy in transporting heavy loads was offset by the larger economy to be obtained through the greater speed of a truck of small capacity. It was very much more difficult to determine the proper carrying capacity for this service, because in suburban territory, the truck in addition to transporting the gang would be required to carry subscribers' equipment, wire, miscellaneous material and tools, the weights of the load varying with the outside plant facilities at point of installation and the number of installations to be made in one day.

"Again, in city work, where block and house cable facilities are provided in advance, the only material to be delivered by truck is subscribers' equipment and inside wire. The chauffeur operating the truck would be required to make the delivery. In this work the congested traffic conditions precluded the possibility of high mileage, and the nearness to the base of supplies made it unnnecessary to consider a truck of greater capacity than was required for one day's deliveries.

"In the delivery of splicers' supplies to the man on the job, the size of the truck to be used as between one of 2,000 pounds and 4,000 pounds is problematical depending largely on the number of men to be served, the radius of operation, the distance from the supply base and the weight of load for one day's deliveries.

"A final analysis of this service indicated that for classes c and d, a truck of 2,000 pounds capacity would meet the average condition and that for class e a truck of 800 pounds capacity should be used.

"It proved less difficult to determine the repair shop's requirements (class f) because the Lansden electrics had been in that service for a number of years and we knew what conditions were involved. When these electrics were put in service, the shop served only the storerooms and central offices in Manhattan, The Bronx and Westchester. With the merging of the New York and New Jersey Telephone Co., taking in Long Island and a part of the State of New Jersey, it was found more economical to close the shops which were maintained in Brooklyn and Newark and serve the entire territory from the shop in Manhattan.

"This wider field of operation necessarily changed entirely the method of shop deilveries. The Lansdens had proven very satisfactory in the congested sections of Manhattan, but their limited daily mileage and speed made it uneconomical to send them on the longer hauls into Long Island and New Jersey. Our study indicated that the operations of electrics should be con-

STATEMENT "A"

Comparison of Motor Vehicles With Horse-Drawn Vehicles

Detail of Operating Expense and Saving made by Three-Ton Trucks Used by Cable Placing Dept.

Annual Operating Expense, Three-Ton Mack Truck Based on Performance of 10 Trucks, Average 10,900 Miles		Approximate Gross Annual Saving on Horse-Drawn Vehicles Replaced by Three-Ton Mack Truck Based on 7 Months' Usage	
Chauffeur's Salary (full time including overtime)	$1,146.50	Truck hire (Aug. to Feb.)	$2,904.20
Garage and washing	240.00	Carfare (Aug. to Feb.)	361.69
Gasolene (.0365 per mile)	397.85	Freight (Aug. to Feb.)	118.00
Lubricants (.0171 per mile)	186.39		
Tires (.055 per mile)	599.50	Total 7 months	$3,383.89
Supplies (Miscellaneous)	54.50		
Repairs	240.00	Approximated annual saving	$5,800.00
Depreciation, interest and taxes	1,020.50	Approximated annual saving by placing cable	500.00
Total	$3,885.24	Total	$6,300.00

Approximated Gross Annual Saving by Three-Ton Mack Truck	$6,300.00
Annual Operating Expense of Three-Ton Mack Truck	3,885.24
Net Annual Saving per Truck	$2,414.76

Digitized by Google

fined to the downtown sections of Manhattan and Brooklyn; that 2,000-pound gas trucks should be used for longer hauls where daily deliveries were required; and 4,000 to 6,000-pound gas trucks for the longer hauls where tri-weekly service would meet the plant requirements.

"After determining the requirements for all of the trucking conditions which we intended to consider at that time, we placed orders with the Mack company for:

17 trucks of 6,000 pounds capacity, equipped with power winches,
1 truck of 4,000 to 6,000 pounds capacity, and
15 trucks of 2,000 pounds capacity.

"Later an order was placed with the Ford company for 10 800-pound delivery wagons.

"All of the trucks other than the 6,000-pound type were to be of standard design. The 6,000-pound trucks were to be equipped with power winches and body of special design. These bodies were to be of two types, one arranged with locker compartments extending over the wheels outside of the loading space which was narrowed down to 5 feet; the other with all of the available space in the clear giving a loading platform 6 feet wide by 13 feet long. The winch specification required two speeds, one of from 20 to 40 feet per minute for loading and unloading heavy reels; and another from 40 feet to 175 feet per minute for pulling in underground and aerial cable. The construction of the winch mechanism must be such as to permit of reverse, in order that at the completion of a cable pull, while tension is still on the pulling line, the drum may be released to allow of the removal of the cable grip.

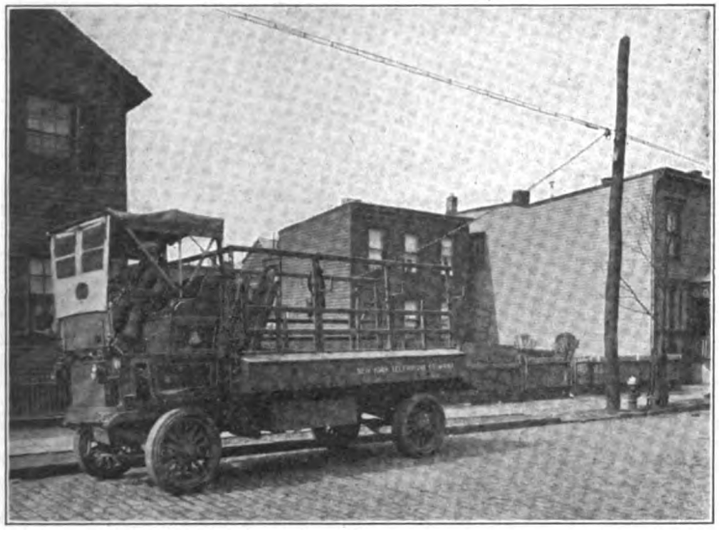
"The manufacturer met all of these conditions by taking advantage of the internal clutch type of sliding gear transmission. Another lever was provided in addition to those used for operating the truck, so that with the transmission in neutral, the operation of this lever would prevent the clutch from engaging the pinion driving through the bevel gears. The intermediate and low speeds and reverse of the transmission could then be applied to the winch through the transmission to a worm driven jack shaft under the winch, thence by chain drive to the winch drum.

"The use of the 6,000-pound winch truck is peculiar to the telephone business in that the actual trucking problem is complicated through the necessity of adapting the truck to hauling of supplies, and when destination is reached, the utilization on the job as a tool in the hands of the plant workmen. The power winch makes it comparatively easy to place a reel of cable 6½ feet in diameter and weighing 2½ tons, on the truck. When the reel is transported to the job, the winch is again used in pulling the cable into the subway or aerial rings. The first saving involved is one of labor in loading; the second, the greater speed of the power truck in getting to destination; and the third, a saving of labor in finally placing cable in the plant.

"A very interesting comparison may be drawn between the truck used continually in extensive aerial or underground construction work, and the truck assigned to a definite area within which it will be used for handling the construction jobs and the repairs and replacements incident to the upkeep of old plant.

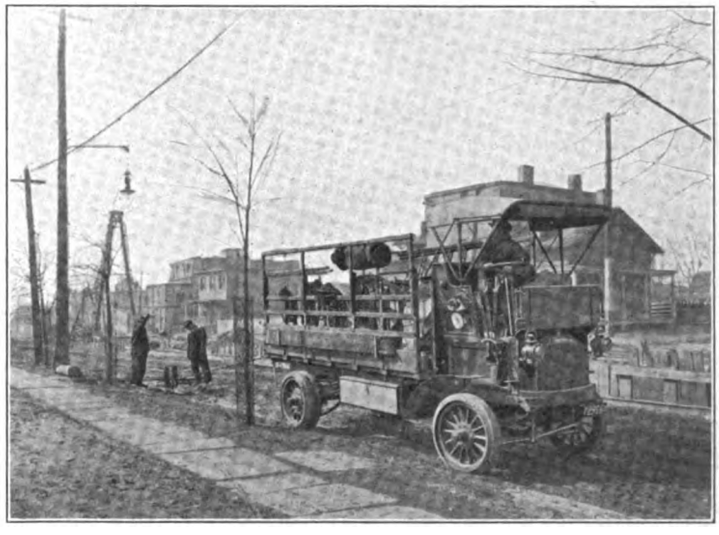
"In the first case, we will take the actual records of the work done by a 6,000-pound winch truck in delivering and placing in the plant 35,391 feet 300-pr. No. 19-gauge and 600-pr. No. 22-gauge underground cable:

Delivery from freight station to job:
79 reels—total weight 153½ tons.
Number of miles traveled—190.
Cost of delivery per ton—$0.84.
Pulling into the subway:
Number of sections—95.
Average number of sections pulled per day—12.
Average number of feet pulled per day—4,464.
*Average winch cost per foot—$.00275.
Returning empty reels to freight station:
79 empty reels returned.
Number of miles traveled—90.
Average cost per reel—$0.93.



*This figure includes all fixed charges on the truck. To be more exact, we should eliminate depreciation on body and frame and tire charges, as the winch is used while the truck is standing idle.

"We have a number of trucks that are used continually in the service as outlined above. The average mileage of such trucks is approximately 11,000 miles per year; that is, the truck is used as a truck more than 50 per cent. of the time, and the saving involved is largely in the cost of trucking as compared to a horse-drawn truck. Statement 'A' gives the estimated yearly operating cost and saving based on actual records of seven months' use.



"In the second case cited, the truck covers approximately 5,300 miles per year, or to express it in different terms, in a working day of nine hours, it is traveling only 22 per cent. of the time. In the territory where such trucks are used, transportation facilities are relatively poor, so that there is a decided economy in having the gang report at headquarters where the truck is to be loaded in the morning, and ride with the truck to the job. Such trucks may cover anywhere from one to five jobs in a day, the men in every case traveling from job to job with the truck.

"The truck is utilized on the job pulling in cable, starting and setting poles, and necessarily stands idle more of the time than in the first case cited, as it acts more as a utility tool in the hands of the workmen, than as a truck.

"Statement 'B' estimates the total cost of operation for such a truck over a period of a year and the estimated saving based on actual daily records maintained over a period of about seven months.

HOW CABLE IS HAULED UNDERGROUND

METHOD OF HANGING OVERHEAD CABLES

Digitized by Google

"In Statement 'A' depreciation is based on a 5-year life. In Statement 'B,' depreciation is conservatively based on an 8-year life. It is clear from a study of the statements, that because of the smaller mileage, it would be fair to assume that depreciation should be nearer 10 per cent per year than 12½ per cent. as is figured.

In the case first cited, it is very easy to determine whether or not the installation of a power truck will effect economies. In the second case cited, territorial and operating conditions must be studied more carefully; otherwise, a power truck which is apparently doing good work may be costing more than a horse-drawn truck.

"Studies made along these lines in a large percentage of the cases show that the use of the power truck proves more expensive than the use of the horse-drawn truck.

"One of the most interesting developments which have followed the use of the winch truck has been the installation of a lead sleeving or other supplies as may be required for carrying on the work. This service has effected a considerable saving over the horse wagon delivery.

"Statement 'C' shows the average operating cost of the 2,000-pound truck. The gross saving effected represents the actual amount of money expended for hired wagons and clerical labor prior to our purchase of power trucks.

"We are not prepared, at this time, to furnish detailed figures on the saving effected through the use of the 2,000-pound truck in aerial loop work. In fact, we have not in any case replaced horse trucks where the entire time of a power truck would be required. We are using eleven 2,000-pound power trucks, where part time is given to loop work and part time to the delivery of pole line hardware, wire and miscellaneous material, used in the aerial plant; in every instance these trucks have been installed where there was no doubt as to the saving to be effected. I might cite a case in the

Total	$2,320.99		

Approximated Gross Annual Saving by Three-Ton Mack Truck	$3,750.00
Annual Operating Expense of Three-Ton Mack Truck	2,320.99
Net Annual Saving per Truck	$1,429.01

*The Chauffeurs operating these trucks are experienced linemen and work with the gang when trucks are standing idle; hence part of their expense is properly chargeable to the work.

derrick for setting poles. Whereas the old method required from six to eight men, and a time element of from 10 to 20 minutes, per pole, the new method requires the services of only two men to hold the butt of the pole in position, while the chauffeur operates the winch in lifting the pole and dropping it into the hole; the time element in this case being from 2 to 5 minutes, or in other words, the cost of setting the pole is practically eliminated.

"A satisfactory hole digger to be used in conjunction with this pole derrick is one of the anticipated developments which will materially reduce the expense of building pole lines.

"In parts of our territory, where we have extensive underground plant, the 6,000-pound truck is used for delivering and pulling in underground cable. After this has been accomplished, the splicing forces are employed in connecting up section lengths and cutting cable into service. The 2,000-pound truck is used as a traveling storeroom, going from job to job, furnishing each splicer with tools, solder, paraffine, Long Island Division where two 2,000-pound trucks replaced four horse-drawn trucks in handling this combination work, effecting a net saving, in truck hire and labor combined, of $2,900.00 per year.

"Prior to the time when a satisfactory motor wagon could be secured at a reasonable cost, the most economical plan of handling subscribers' installations was to have the installer carry with him to the job the apparatus to be used. This necessitated the workman reporting at the storeroom each morning to get his equipment and returning there during the day as apparatus was required for other installations. It is quite apparent that, in handling installations in this manner, much time was lost by workmen in traveling from storeroom to the job and returning to the storeroom when additional material was needed during the day.

"By relieving the installer of carrying material, or by reducing the time required in this particular phase of the work, more of his time could be applied to the actual installation. This result had been partially accomplished in the past through having six retail storerooms on Manhattan Island —the installation forces operating by districts, with the nearest storeroom as district headquarters.

"In utilizing power wagons for delivering equipment directly to the subscriber's address, the first economy effected is through cutting down the installer's traveling time, as, instead of reporting to the storeroom in the morning, he reports directly to the subscriber's address where the installation is to be made. The second economy is effected through closing the six retail storerooms and making deliveries from one central point, and by this centralization reducing the supply investment. The third economy is the result of operating a centralized minor repair shop in conjunction with the storeroom. When six storerooms were operated, it was necessary to make minor repairs to apparatus recovered within each of the six storerooms. With centralization, the volume of repairs at once became great enough to prove in piece work, thus effecting an economy in actual repairs, and a further economy in that work could be supervised by one foreman instead of the six required to operate the smaller repair shops under the district system. This centralization naturally brought about a considerable saving in clerical routine also.

"By locating the central storeroom in the same building with the Western Electric Company's warehouse, it was possible to cut down the average time of delivery from warehouse to distributing storeroom from one week to a few hours.

"The routine covering the handling of deliveries is as follows:

"All contract, plant and memorandum orders, on which apparatus must be delivered, are prepared at the close of each day by the night order force from subscribers' contracts, inspectors' recommendations, and written requests from subscribers for change in apparatus, received up to 5 P. M. on the same day. Copies of all such orders are delivered at the central storeroom prior to 5 A. M. of the next day. These orders

Digitized by Google

are then assorted by address into delivery districts and turned over to selectors. Cardboard containers are provided, designed to take complete standard station equipments of various types, including directories. These containers are stamped with the type of equipment which they contain, and the selector attaches thereto an envelope containing a copy of the contract order, noting on the outside of the envelope the delivery address.

"Packages to be delivered by each wagon are then placed on hand trucks in the order in which they will be loaded on the wagons; that is, routed by deliveries. The wagons report at 7:30 A. M., are loaded with equipment, the drivers are given copies of their respective route sheets, and by 8 A. M. have started to make deliveries.

"Apparatus disconnected at subscribers' premises is removed by the workmen to the nearest central office, from which place collections are regularly made by the power wagons and the material returned to the central storeroom. Our average cost per delivery, including all charges, is $.114; our average cost per recovery, $0.21. The average cost of delivery by horse-drawn vehicle, which was tried out before we decided to purchase power wagons, was $.176. The use of power wagons in connection with this Central Storeroom has reduced our annual expense from $79,624 to $64,037—a net saving of $15,587 per year.

"The Shop service presents a straight delivery problem, comparable with any outside trucking business, and for that reason will not be gone into in detail in this discussion.

"Statement 'E' shows the expense of operating the 4,000 to 6,000-pound truck used by the Shop for the year 1911, from the time it was put in service, up to and incpluding December. A similar record is maintained for all of the 53 commercial vehicles, 14 touring cars and 97 runabouts owned by the company. Data are taken from daily reports sent in by the drivers, and at the end of each month the supervising forces are provided with these statements which show the expense of the current month, and all the previous months in the year.

"It seems probable that the telephone man, not directly interested in outside plant work, does not realize the magnitude of the trucking problem involved in building and maintaining telephone plant. A perusal of this article might, therefore, lead most of us to believe that the company had entered more extensively into the use of power trucks than a proper degree of caution would seem to warrant. As a matter of fact, we are hiring on the average, approximately five times as many horse-drawn trucks as we have power trucks in service. Our total expense for hired trucks during the year 1911 amounted to $385,559. It is estimated that 50 per cent. of this expense was due largely to the very extensive outside plant development work carried on during the year 1911.

"We now hire approximately 100 horse-drawn trucks per day. A large part of these are used in loop work, and it is safe to assume that we will continue to hire trucks for this service for a number of years to come, or until such time as a power truck is developed which can be purchased at a price bringing the annual charges as low or lower than the annual charges on the horse-drawn truck. This holds true because the nature of the work keeps the truck in the field, but idle, for a large part of the working day. Hence the problem is not one of economy in transportation so much as economy in standing idle.

"In the traffic congested sections of a city like New York, our experience has been that we could not afford to use power trucks of other than the inexpensive light delivery type. The horse-drawn truck is so much in evidence that the power truck is limited to about the same speed with an investment approximately three times as great. Here the horse-drawn truck must be eliminated before the power truck can come into its own."

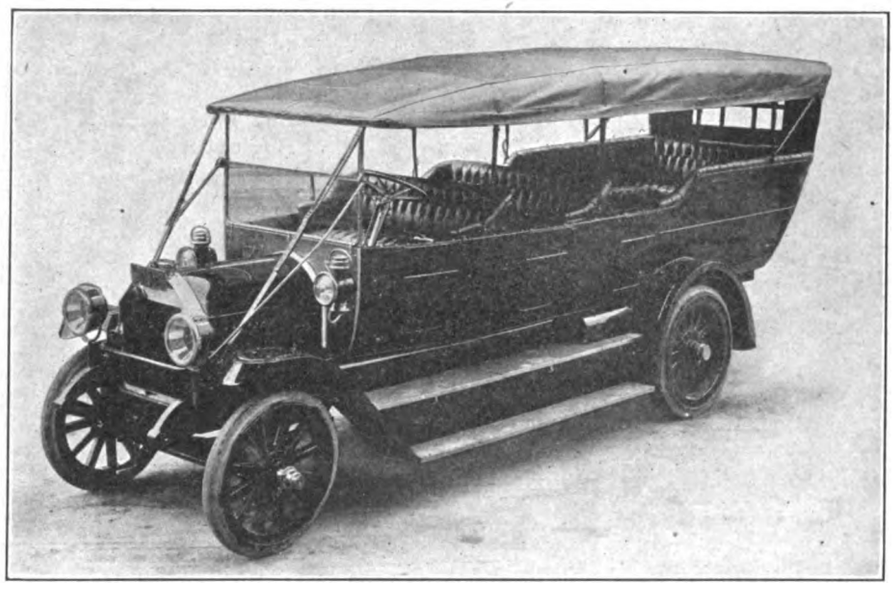
Fifty Runabouts For Telephone Use.

Having obtained a full measure of success with its Sampson trucks, 20 of which have been placed in service during the past year, the Western Electric Co. has still further increased the efficiency of its organization by the purchase of 50 Brush runabouts for the use of the linemen of the New England Telephone & Telegraph Co. At the same time, a Stoddard-Dayton "Saybrook" four-pasenger touring car was purchased for the use of the Telephone company's division superintendent at Boston.

England Extending Motor Mail Service.



As a direct outcome of the successful venture of transporting mail matter by motor truck from London (Eng.) to Birmingham, British postal authorities are preparing to place themselves in a position where they will be still less dependent on the railroads and shortly will extend the service to include Manchester and intermediate points. The new service is planned along the same general lines of the old, which has been in effect a little over a year with gratifying results, post office employes traveling with the trucks and sorting the mail en route. Stops will be made at several intermediate points for collection and distribution, the trucks being capable of carrying 4,640 pounds, which it is estimated will permit the transportation of some 20,000 pounds of matter a week. Two trucks will be used and they will be started from either end of the route at such time as will permit their arrival at Manchester and London at about 6 o'clock every morning. The success of the service, says Consul Albert Halstead, of Birmingham, in substance, indicates that the British General Post Office will by degrees largely increase the carriage of parcels by motor truck, which development of mechanical traction, he continues, shows a most decided upward trend, not only large commercial firms, but also companies engaged in collecting, carrying and delivering freight gradually turning to motor trucks in preference to the railroads, which have for a long time enjoyed a trade which has almost amounted to a monopoly.

"RUBBERNECK" WAGON MODERNIZED

Detroit Designers Evolve a Body Suggestive of the Touring Car—Seating Capacity Ingeniously Retained.

In attacking the problem of producing a passenger bus that shall be serviceable as well as of pleasing appearance, the General Motors Truck Co., Detroit, Mich., has cast out conventional designs entirely and brought out a brand new type of vehicle that scarcely can fail to prove popular with the sight-seeing public. As a general rule, those who have occasion to ride in sight-seeing buses give little concern to the appearance of the conveyance; they are there to see and unless they are unusually fastidious it makes little difference to them whether they are seen or not. Still, even the most fastidious passenger could have little fault to find with either the riding qualities or the appearance of the latest product to be marketed under the insignia G. M. C.

G. M. C. BUS THAT RESEMBLES A HUGE TOURING CAR

It is not an easy matter to design a well-appearing bus, because of the necessity for the maximum seating capacity available. Consequently most buses appear clumsy and top-heavy, and in the majority of cases they live up to their appearances and are neither easy to handle nor are they the acme of comfort from the passengers' point of view. In the new G. M. C. bus, however, a pleasing exterior has ben obtained by following closely the general lines of accepted practice in touring car design and as a result the vehicle does not in the least resemble the usual type of "rubber-neck" wagon. As may be seen by the accompanying illustration the vehicle resembles more the conventional touring car, except that it is rather elongated, the wheelbase being 142 inches, the resemblance being increased by the high flush sides and enclosed driver's compartment.

Even in the matter of seating arrangement the bus resembles an ordinary touring car, there being two cross seats behind the driver's seat and a big roomy tonneau. The total seating capacity is 16 passengers, not counting the driver, and entrance to all the seats is effected by means of side doors. The body is mounted on a standard model two-ton G. M. C. chassis, the engine being of the four-cylinder, vertical, water-cooled type and having cylinders which measure 4x6 inches bore and stroke, respectively. Power is transmitted from the engine to the rear wheels through the intermediary of a dry multiple disc clutch, four-speed selectively operated, change gear mechanism and side chains. The first of the new buses to be finished already is in service in Seattle, where it is employed to convey sight-seeing parties through the Rainier National Park.

Two Buttons For Six-Cylinder Starters.

It is not always possible to start a six-cylinder motor equipped with an automobile gas starter simply by depressing the starter button on the dash, for unless the crank shaft is in such a position that the circuit breaker of the magneto is closed, no spark is produced in any of the cylinders, and firing is therefore impossible. Shifting the spark lever sometimes will close the gap, but the practice is not to be relied on. If a second push button is "bridged" across the terminals of the breaker, however, a spark always can be produced simply by depressing both buttons at the same time and the engine starter thus is made much more reliable.

Rim Attention That Is Worth While.

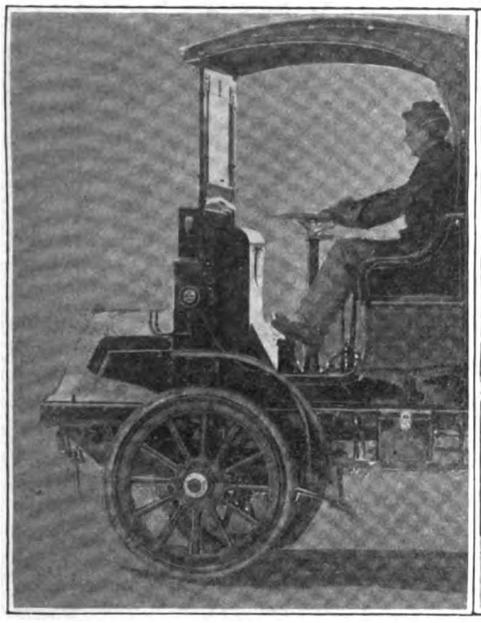
Though many times it has been advised that rims on which quick-detachable tires are mounted be cleaned periodically, the reiteration of the advice serves to give emphasis to the fact that such proceeding is essential if the tires are to live up to their calling and present no difficulty to quick and easy removal. The advice is especially timely in the spring, when the roads generally are moist, to say the least. Experience points that unless quick detachable tire rims are kept in good condition, free from rust and dirt, the removal of tires may be a great deal harder than it would be if the rims were of the clincher type. This may be explained by the construction of the clincher rims which is such that there is less opportunity for water and dirt to work in between the tire and the rim. However, clincher tires often are just as hard to remove as quick-detachable tires, and if difficulty is to be obviated care must be taken to keep the rims clean.

Why Tire Chains Require Attention.

Though it has been advocated that tire chains should be so adjusted that they "creep," in order to cause even wear all around the tire tread, care should be taken to see that they are not loose enough for the cross chains to strike the mudguards, in which event not the least damage which may be expected will be the loss of paint from the guards; the chains themselves may be broken and lost. The noise of a chain incessantly slapping against the mudguard is an abomination, of course, and it is a simple matter to tighten the chains a little, or, if a cross chain is broken to cut it off with a cold chisel and a hammer. When a cross chain is removed, however, a new one should be put in its place at the earliest possible moment. Otherwise there remains a large enough section of the tire unprotected by a chain to cause a violent skid, which always is imminent under such circumstances, because with the brakes applied the wheel will continue to rotate, traction being maintained by the chains, until the bare spot comes in contact with the road when the wheel will slide.

Indication of a Worn Needle Valve.

A carburetter that persists in dripping when the throttle is closed usually will be found to have a worn needle valve that requires grinding to its seat. Use a very fine grinding compound for this work, one which is not composed of emery, the particles of which will embed themselves in the brass and keep the valve and its seat in bad condition.



In time an accumulation of carbon is likely to result from the practice of turning off the gas and letting the acetylene lights die out. While an occasional cleaning of the burners is not a serious job, it can be avoided by blowing out the lights first and turning off the gas afterward, according to the suggestion that comes from abroad. It is somewhat of a question, however, whether the game is worth the candle, but in any case the blowing out of the lights is apt to be followed by a waste of gas, if nothing worse happens, should the shutting of the valve be neglected.

TRUCK PROBLEMS: PROTECTION FOR THE RADIATOR

Rarely Considered by the Average Person, This Necessity Affords Remarkably Wide Scope for Engineering Ingenuity—Varying Devices and Designs That Have Been Developed and That Are Employed—Position of Radiator and Not Protecting Devices a Solution Often Advocated.

An ounce of prevention, so the saying goes, is worth a pound of cure, and in no field of endeavor has the truth of the adage been more clearly demonstrated than in the design and manufacture of motor trucks. Intended for rough work in rough places, so to speak, there is need for preventives, which, if not wholly unnecessary on pleasure cars, are inadvisable or so stout or heavy as to detract from their appearance; therefore when they are employed on cars they assume lighter or more ornamental shapes.

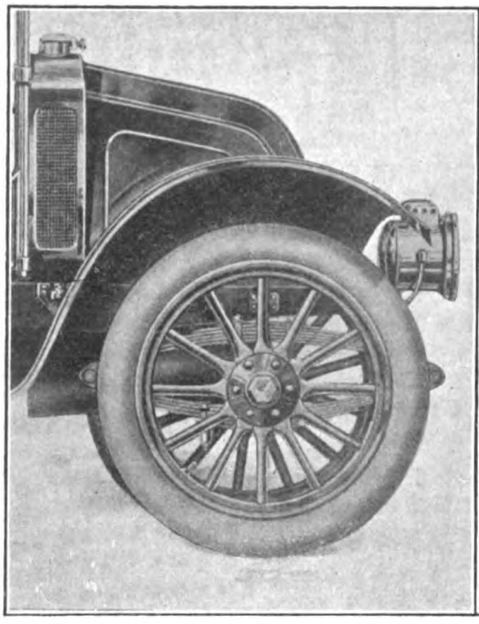
GRABOWSKY CONSTRUCTION

AUTOCAR FRAME FENDER

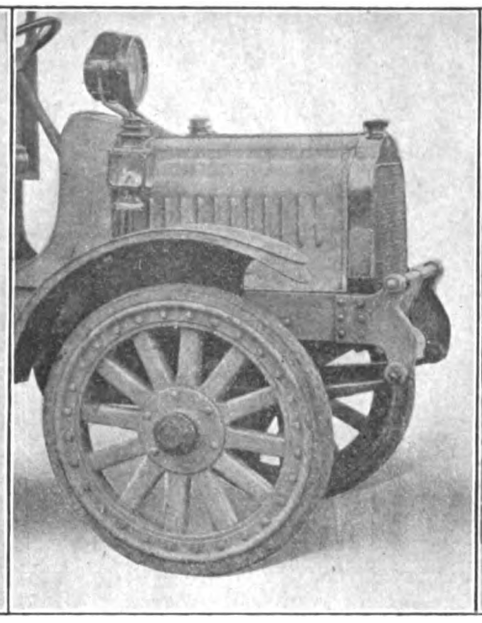
SPEEDWELL RADIATOR GUARD

Protection for the radiator is a case in point. Radiator construction, that is, the construction of the cooling surfaces themselves, varies but slightly in commercial car practice from the construction adhered to in pleasure cars, and the inherent trailness coupled with the forward location, which generally is adhered to renders it a particularly vulnerable point at all times and especially in the case of vehicles frequently used in congested traffic. Rigidity of the radiator frame, the method of mounting it on springs so that the warping of the chassis under heavy load or bad road conditions has little or no effect, and means of protecting the radiator from injury are points which distinguish commercial vehicle practice from pleasure car practice.

The traffic conditions under which the commercial vehicle works, amid trucks both horse drawn and motor propelled, laden with all sorts and sizes of articles, and the class of help into whose care the vehicle is entrusted, make the protection of the radiator a not unimportant problem. The solution which perhaps is the first to be thought of is to shift the position or the location of the coloing device to a more protected spot, and, indeed, this has been resorted to with success in several instances. On the Lippard-Stewart truck, for instance, the radiator is located directly in front of the dash and partially straddles the motor, in a manner similar to foreign pleasure car practice. The location has much to recommend it, for besides the excellent protection from injury through collision, a degree of accessibility is reached which only in rare instances obtains where the forward location of the radiator is adhered to. The position of the radiator is such, however, that the use of a fan to render cooling more certain when the vehicle is standing with motor in operation is more difficult.

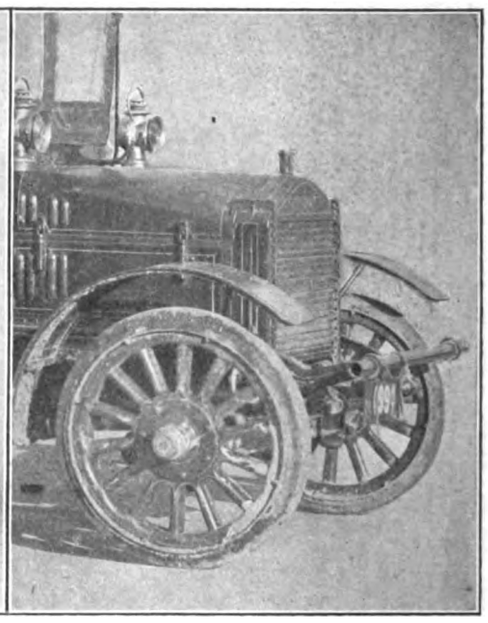


HEWITT RADIATOR GUARD



An unusual practice where the radiator is located on the dash, is to position the radiator so that the bottom clears the top of the hood. The air then has free passage through the radiator to a hood, which houses the fan, and which encloses the radiator on the side facing the driver. It serves to conduct the air below the floor boards. This position does not detract from the cooling qualities of the radiator, and still it is fully protected, and the accessibility of the motor is unimpaired. The practice is exemplified by the Grabowsky wagon, wherein the motor is housed forward in an accessible position in front of and below the radiator.

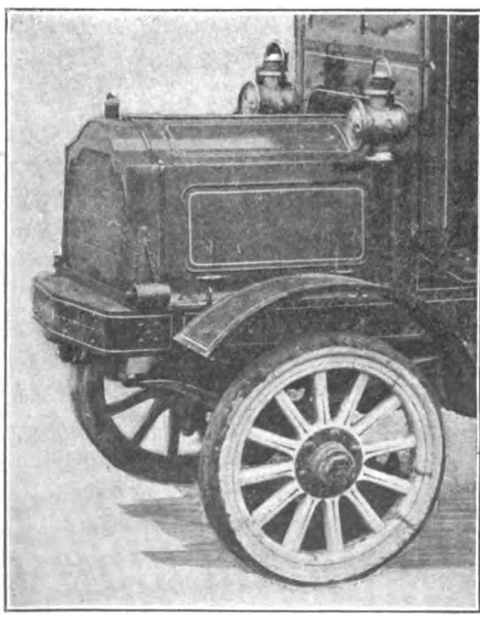
The use of a bumper to ward off the blows which otherwise would demolish the



Digitized by Google

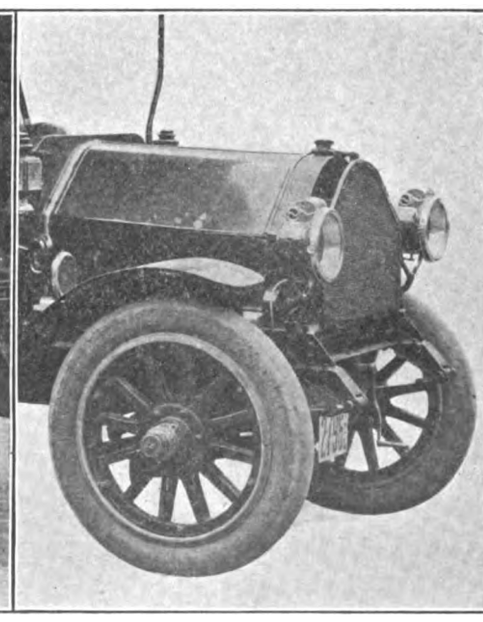
LIPPARD-STEWART DESIGN

WALTER RADIATOR FENDER



PIERCE-ARROW BUMPER

comparatively frail radiator, is much commoner on the commercial vehicle than is the case on pleasure motors, and as a rule, the bumpers are of more rugged construction. Unlike pleasure car practice, the bumpers generally are riveted directly to the side frame members without the intermediary of springs to partially absorb the impact shocks. On the Pierce-Arrow the bumper takes the form of a straight tubular bar supported rather low with regard to the radiator by two drop-forged hangers, while Walter trucks employ a solid bar supported by two rather heavy brackets which serve also to anchor the forward ends of the supporting springs.



The bumper used on the Autocar is more or less distinctive, being formed of channel steel of rather smaller cross section than the frame member, which is curved around the low hung radiator in the shape of a bow. Speedwell practice is somewhat similar, in that the radiator is hung low and the bumper is of channel steel.

With a great many of the commercial vehicles, especially the heavier trucks, the bumper consists of nothing more than an extension of the main frame, the front cross member serving to protect the more vital parts of the machine. This practice is followed both when the motor is mounted under a hood, as is the case with the Packard, and when mounted under the driver's seat, as exemplified by the Gramm.

One of the most radical departures in a method of radiator protection has been worked out by the designers of the Hewitt truck, who, working on the theory that the radiator is susceptible also to shocks of lesser magnitude, have fully protected the radiator by covering it with a heavy wire mesh screen, which is bolted directly to the radiator frame. This protective screening is capable of withstanding quite a heavy blow. The Velie also employs a wire netting before the radiator, supported by brackets, which keep it about half a foot from the cellular radiator. The Eckhard truck has a radiator of very rugged construction, which is protected by a frame extension and also by an iron grating bolted to the radiator frame. In fact, the positioning of the radiator and the providing of means for its protection is an interesting study in itself, and involves far more thought than appears on the surface, even to those who own many trucks.

WHEN GASOLENE COMES IN SEALED PACKAGES

The "Designing Engineer's" Assistant Takes Another Long Look Far Ahead and Sees Standardization Now Unthought Of — There Are Obstacles, He Admits, and His Dream Is Interrupted But He Persists, Nevertheless.

"Hello, 'Foureyes,' I just came up to get an insight into the spring wheel trade as it will be in 2012, for I guess you must be ripe to tell me what will be the final design of those 'Rubber Trust' busting devices," exuberantly exclaimed the man from down stairs, as he took a seat at the draughting table opposite the designing engineer's second assistant.

"Look here, young fellow, you're in the wrong place, and likewise you are talking to the wrong individual," chuckled the second assistant. "Take up a newspaper and glance at the 'Personal' column until your eye lights on the name of a good clairvoyant. You know the kind—one of those crystal charmers who can tell you your name if you supply all of the letters, and who will guarantee to lay bare your past, present and future for the insignificant sum of five dollars. If you can't obtain an accurate description there, I guess you never will. Anyhow I'll never attempt to even describe the spring wheels we have now, much less those which are to come."

"Well, well, well, well!" was the taunting response. "You do not mean to tell me that the subject doesn't hold enough interest to make your attention worth while, do you?"

"I won't put it that way. I'll just say that the subject is a trifle too deep for me and let it go at that."

"H-m-m! That's too bad. I fancied that I was introducing a subject of endless possibilities, a subject on which you could talk from now until doomsday without thought of draining you dry. I thought probably you had exhausted your fund of information on the question of fuel economy and would unwind a dissertation on something else. I am just in the humor to listen to one."

"One thing at a time. I told you the last time you were up here that I had in mind 101 different ways for the conservation of fuel, and I only mentioned two. For this fuel-saving proposition is every bit as interesting and inexhaustible as the spring wheel subject, and not nearly so monotonous. Why, I hardly can glance over the papers without seeing something which makes me think of the design of the motor cars of the future. Did you read the papers this morning? Notice that article on the banquet of the In-Er-Seal Society?"

"Why, yes; but for the life of me I can't see what connection a 'blow-out' of the selling force of the National Biscuit Co. has with the reduction in the price or on the use of liquid fuel in automobiles."

"You're not as bright as I thought you were. But you hold your horses and maybe I can show you the connection. There was a time, not very long ago—you remember it and I remember it—when soda biscuits, or soda crackers, as we used to call them, came packed in large wooden boxes. They were sold by weight, and a pound would fill a large bag to overflowing. Still there were times, after a siege of damp weather generally, when the crackers would become soggy and moist and unfit for use. Then someone got an idea and jumped at it. A neat little carton built of paraffined cardboard and lined with paraffined paper was designed, and the biscuits were placed in these moist-proof packages immediately after being taken from the oven. Proper exploitation of the advantages of the 'In-Er Seal' packages, coupled with a well-managed advertising campaign, embodying a well-chosen name for the product, produced results truly wonderful, so that nowadays most of the crackers we purchase are packed in moisture-proof packages, and the sales are so enormous that the companies' salesmen now have an annual 'feed' and jollification. The reasons for the success of the products so packed are more or less self-evident — cleanliness and convenience.

"The practice of packing things, or protecting the foodstuffs from the ill effects of the atmosphere and from the hands of meddlers has extended considerably since that innovation, so that we now purchase our bread, our butter, our tea, coffee and cereals—in fact, an endless number of things, packed either in oil paper or in cartons. And the practice is not confined to foodstuffs, either. Articles of clothing, handkerchiefs, collars, etc., come done up in sealed packages so the meddling hands of the 'bargain rusher' in no wise impair the appearance or value of the articles themselves, and substitution on the part of the tradesman is impossible.

"Sh-h! Don't interrupt me.

"Now consider the relation of all this to the automobile industry. For the last several years there has been a very marked tendency which has spread so that most of the major parts of the modern machine are designed within limits. All of the screws, nuts and bolts are cut standard. The designers of motor trucks now are agitating the adoption by the S. A. E. of limits for truck chassis design, limits which include capacity and speed as well as flexibility. All this standardization leads toward one end—interchangeablility which spells convenience. It is not at all unlikely that in the years to come the practice of making things standard and hence more or less interchangeable will reach the fuel tank and a standard location will be chosen, a standard capacity adopted according to the power of the motor, a standard contour or shape of course will be the vogue. The location probably will be determined by the method employed to feed the carburetter; if gravity feed is provided for by the designer, the location will of necessity be chosen so that the gradient of the road will in no wise impair the flow of the liquid; with the force fuel feed the tank can be placed lower than with the gravity system, however, the tank will be placed in a position readily accessible. Tanks, intsead of being supplied with the cars, as a part of the cars, will be supplied as a unit similar to the gas lighting tanks, now so common. The turn of a thumb screw will suffice to fasten the tank in place in the brackets provided for by the manufacturer and some kind of an automatic coupler will insure the rapid and positive connection with the fuel supply pipe.

"Do you see the connection now? The gasolene, alcohol, or whatever the future fuel will be, will come supplied to the consumer in sealed tanks. This will make for safety and convenience in handling and will insure the quality as well as the quantity of the fuel supplied, for both will be guaranteed by the corporation or corporations which charge the tanks. The seal naturally will preserve the contents from being disturbed by the garage man and evaporization of the lighter elements likewise will be prevented."

"Oh, yes; I follow you perfectly, but I'm afraid you are flying your kite too high. A tank to hold 45 or 50 gallons and be strong enough to be portable and resist the tendency to be dented and bent beyond recognition must be made of rather heavy material, and the weight of the fuel itself, added to the weight of the container, would go a great way toward limiting the adoption of the interchangeable sealed tank fuel supply system, on the grounds of convenience, at least."

"Who said that the tank was to hold anything like 50 gallons?"

"Well, most of the cars you see nowadays carry sufficient fuel for a half-decent run. It is not likely that the designers of the future are going to limit either the scope of the vehicle or so limit the dimensions of the fuel tank that refilling will be necessary. That stands to reason."

"Right, and yet the fuel tanks are going to be smaller, according to my way of looking at it, and the condensation will be brought about by retreatment of the fuel—retreatment which will make it contain many more heat units per unit of weight than the fuel now employed, which will mean that less fuel will have to be used to produce the same power and as a consequence either the radius of operation of the vehicle will be increased, or the fuel tank will be made smaller. Then, too, so

Digitized by Google

many things will have been done in the way of motor improvement that the consumption of fuel per brake horsepower will be greatly diminished, if I am not greatly mistaken."

"But——"

"How? Oh I don't know. I have a faint idea, but my friendship with the organic branch of chemistry is not sufficiently well developed to permit me fully to explain. Roughly, I think it will be something like this: The available heat units in a pound of gasolene are in round numbers 20,000, while in an equal quantity of hydrogen there are three times as many. Obviously the introduction of hydrogen into the gasolene would produce the desired effect. Just how this will be done, time will tell, but that it will be done I am certain. Synthetic chemistry, although practically in its infancy, has produced many, many articles of commerce at a price much below that of the natural article, and from sources unsuspected as the abode of such articles or products. For instance aniline colors, in years gone by, were obtained by the rather costly process of distilling indigo. Today practically all of the colors are obtained from petroleum products, from the coal tars which formerly were thrown away as waste products, and the change has been brought about by research work done by chemists. Very many similar cases could be named, but I will spare you. Really, now, it does seem to be within the bounds of possibility that the fuel of the future will be 'superheated' in some way or other, doesn't it?"

"Better ask your chief, I'm not encouraging such dreams," and with a quizzical smile the man from down stairs made haste to return to his desk.

1,005,626. Adjusting Mechanism for Lamps for Automobiles. Arthur James Farrell, Pittsburgh, Pa. Filed May 5, 1911. Serial No. 625,138.

In a lamp adjusting mechanism for vehicles provided with a steering gear, a worm on the post of the steering gear, two vertical lamp supporting shafts journaled in bearings carried by the side frames of the vehicle, a beveled pinion on the lower ends of each shaft, a pair of horizontally extending shafts journaled in hangers carried by said side frames, beveled pinions on the forward ends of said shaft and meshing with the pinions on the lower ends of the vertical shafts, beveled pinions on the rear ends of said shafts, a transversely extending shaft journaled in hangers carried by said side frames and provided with beveled pinions meshing with the pinions on the rear ends of the horizontally extending shafts, a worm wheel on said transverse shaft meshing with the worm on the steering post, rearwardly extending cranks carried by said vertical shafts, and a connecting bar pivotally attached at its ends to said cranks.

1,005,627. Tire. Michel F. Fiset, Jr., and Louis A. Fiset, Albany, N. Y. Filed Nov. 21, 1910. Serial No. 593,581.

1. A tire comprising a casing, a plurality of individual resilient cells mounted in the casing, each of said cells having an open end and an enlarged portion which abuts against the adjacent cell, and a metallic cap fitted over said open end and bearing on the inner surface of the casing.

1,005,845. Odometer. Joseph W. Jones, New York, N. Y. Original application filed Aug. 7, 1908, Serial No. 447,447. Divided and this application filed Oct. 4, 1909. Serial No. 520,948.

1. The combination of a numeral disk or wheel adapted to be rotated in a forward direction to give a desired indication; a spring exerting tension to rotate the disk in a rearward direction while permitting unlimited rotation of the disk in the forward direction, one end of said spring having fixed connection to the disk and the other end of said spring having an anchorage adapted to be shifted by the forward rotation of the disk; means for retaining the disk in any position to which it is moved by forward rotation thereof; means operable to release said retaining means thereby freeing the disk to be rotated in a rearward direction by said spring; and means for arresting the disk in a zero or starting position when thus rotated by the spring.

1,005,863. Automobile. William L. Miggett, Ann Arbor, Mich. Filed Dec. 31, 1909. Serial No. 535,730.

1. In an automobile, the combination of two driving wheels, a shaft adapted to drive each of said wheels, said shafts converging toward a point at a distance horizontally from the axis of said wheels, and a balance gear located adjacent to the point of convergence of said shafts adapted to rotate said shafts and to permit independent motion of said shafts.

1,005,873. Tire Protector. Charles .R Ragsdale, St. Louis, Mo. Filed June 2, 1910. Serial No. 564,546.

1. A tire protector comprising a plurality of pairs of laterally curved shields formed with outwardly turned hooks on their sides a plurality of pairs of oppositely disposed spring-controlled hooks mounted inside the felly, a plurality of pairs of fixed hooks supported on the sides of the felly but outwardly of the spring-controlled hooks, and flexible connections extending between the sides of each pair of said shields, the fixed hooks and the spring-controlled hooks.

1,005,960. Pneumatic Tire. Robert B. Gray, Port Carbon, Pa. Filed Oct. 14, 1909. Serial No. 522,579.

In combination with an outer tube, a series of open-ended separate tubes of varying diameters within the same, and removable collectively or individually therefrom, a normally-closed air chamber arranged transversely within the casing and comprising an outer wall an inner wall.

1,005,962. Non-Pneumatic Elastic Tire for Vehicle Wheels. Oscar Grenier, Boulogne-on-the-Seine, France. Filed Oct. 11, 1910. Serial No. 586,451.

In a non-pneumatic elastic tire for vehicle wheels the combination of an inner tube, balls and plugs embedded in said tube, single strips made of suitable material and

forming independent sections wrapped around said tube and an outer tube inclosing the whole and a tread cover adapted to receive the outer tube.

1,005,969. Explosive Engine. Charles D. Heaton, Jr., Providence, R. I. Filed June 22, 1910. Serial No. 568,318.

In an engine, in combination with a plurality of cylinders, the outer end walls of the cylinders being formed with valve seats, a valve including a rod of solid cross section disposed in said seat and having portions projecting on opposite sides of said cylinder walls, said rod being formed with an inlet and an exhaust port for each cylinder, said ports being of substantial arc-shape in cross section and having mouths of sufficient length so that the ends of the mouths extend beyond opposite sides of the cylinder end walls to establish communication between the cylinder interior and exterior and a casing for each valve port carried by the cylinders.

1,006,017. Variable Speed Gearing. Charles C. Spinks, Washington, D. C., assignor to M. C. Spinks and M. A. Poor, Memphis, Mo. Filed July 2, 1910. Serial No. 570,100.

1. In a device of the kind described, a shaft having an eccentric head, a mutilated gear loosely mounted on said head, and having a radial recess, a stationary pin extending into said recess, an internal gear adapted to be engaged by the first mentioned gear and given a step by step movement, a second shaft, a gear on said second shaft, and a larger gear connected with the internal gear and meshing with the gear upon the second mentioned shaft.

1,006,033. Carburetter. Garhardus L. ter Weer, Detroit, Mich., assignor of one-third to Sybren R. Tymstra and Johannes H. Figee, Detroit, Mich. Filed July 19, 1909. Serial No. 508,327.

1. In a carburetter, a conduit adapted to connect with an engine, a vertically disposed air conduit open at its lower end and communicating at its upper end with said first mentioned conduit, said air conduit being provided with a valve seat at the top thereof and intermediate the ends thereof and directly below said valve seat with an enlarged portion therein, an oil feed nozzle positioned centrally of the enlarged portion of the air conduit, and an open ended double cone valve positioned in the air conduit and surrounding the oil feed nozzle, the upper end of said valve being normally seated on the valve seat at the top of the air conduit and the lower end of said double cone valve extending below the point of greatest width of the enlarged portion of the air conduit.

1,006,055. Vehicle Wheel. Edward S. Bottomly, Martinsburg, W. Va., assignor to The Walk Auto Tire Company, Martinsburg, W. Va., a Corporation of Delaware. Filed Apr. 27, 1911. Serial No. 623,746.

1. In a wheel, the combination of a wheel center having a rim, a felly of larger internal diameter than the external diameter of the rim, and pairs of spiral springs interposed between the felly and the rim, each spring having a contracted outer end and a projection on its lower end extending toward and under the adjacent spring in the pair, and provided with a lug on its extremity to assist in positioning such spring; with a clamp plate interposed between the springs in each pair and engaging the extensions of both springs, a bolt for securing said clamp plate rigidly to the rim, and bolts passed axially through the outer coil of each spiral spring and securing the same to the felly.

1,006,064. Starting Device for Automobile Engines. John S. Clarke, East Cleveland, Ohio, assignor of one-half to Alexander H. Langell, Cleveland, Ohio. Filed Nov. 14, 1910. Serial No. 592,282.

1. In a starting device for automobile engines, an engine having a crank shaft, in combination with a tank and a fluid motor having valved communication therewith, and means connecting said crank shaft and said motor comprising separate gearing adapting reversal movements of said motor and separate means to control independent operations thereof for the purposes described.

1,006,219. Vehicle Wheel. Arthur C. Huckelbridge, Coldwater, Kan. Filed Feb. 8, 1911. Serial No. 607,353.

In a wheel, a combined rim and tire formed circular in cross section, said rim being formed in two co-acting sections, one of said sections being of lesser size in cross section than the other section, means for attaching the lesser section to the larger section to permit access to the interior of the rim, a pair of flanges formed integral with the larger rim section and projecting annularly and inwardly therefrom, said larger rim section between the flanges being provided with a series of equi-distantly disposed apertures communicating with the interior of the rim, a hub,

BENZ

¶Since the introduction of BENZ cars to the motoring public of America, agencies have been desired, in fact, coveted by many. We are now in a position to offer agency propositions to responsible parties. ¶Also makers of the famous BENZ-GAGGENAU six ton trucks. Choice territory open for agents. Write us today for full details.

4 Square Reasons Why You Should Choose the Glide

Our New Model 36-42 H. P.

Complete Equipment

$1550

The careful buyer, and the dealer who is alive to the real automobile situation are invited to write for handsome FREE book and learn from this book why the Glide is ***best.*** Booklet pictures and describes full line including Two and Four-Passenger, 45 H. P. Cars, $2,000; Five-Passenger "45," $2,150; Seven-Passenger "45," $2,250.

EFFICIENCY For style, comfort, luxury, quality of construction, mechanical perfection—in all that goes toward a car's efficiency, the buyer of a "Glide" actually gets more automobile value than can be obtained from cars costing at least $1,000 more.

SERVICE The "Glide" is not the only first-class car on the market, we admit that. But unlike other automobiles, the "Glide" is not merely a "one-year" car. We make the "Glide" for 5 to 7 years' continuous service. This we guarantee.

PRICE While the "Glide" is not a high-priced car—remember it is not a cheap car. The standard of construction equals that of cars costing the highest price. Consequently the buyer gets a car second to none in quality at a cost that's as low as any standard make.

GUARANTEE The purchaser of a "Glide" is protected by a guarantee more liberal and wider in scope than any other guarantee ever issued. Read it in the FREE book—sent on request. It will surprise you.

New Selling Agencies

are now being established in select territory. If interested, write us for our special proposition. "Glide" dealers can offer their trade a car that combines quality and service that at the price has never been equalled. Get this FREE book and full details.

The Bartholomew Company
220 Glide Street, Peoria, Ills.

We make cars of all kinds for all occasions and purposes. FREE book pictures and describes the full line, send for it.

Attached Like a Muffler

The experiment illustrated above shows the actual results of a steady 10-hour run of a 50 h. p. engine, first with gasoline, than with the Kerosene Gas Producer and kerosene.

The Kerosene Gas Producer develops the same power and efficiency as gasoline at a saving of $4.83 for the day's work. This pays for the Producer and leaves a snug profit in less than a month.

KEROSENE GAS PRODUCER

Runs Any Gasoline Engine on Kerosene

No Carbon No Smoke No Smell

NO FEAR OF FIRE OR EXPLOSION

The Kerosene Gas Producer is more than economical. It is SAFE. It eliminates danger of fire or explosion. It reduces insurance charges.

The Kerosene Gas Producer is guaranteed to give a clean exhaust, with no carbonization or fouling of the cylinders. It is easily attached, simple in operation and will outlast any engine.

If interested in saving almost 50 per cent. of your fuel bill, clip and fill out the following and mail to Dept. H.

1. Make of engine.....
2. Automatic or manual control.....
3. Number of cylinders.....
4. Two or four cycle.....
5. Are exhaust and intake on opposite sides?.....
6. Speed, R. P. M.....
7. Lowest R. P. M.....
8. Highest R. P. M.....
9. Bore .....
10. Stroke .....
11. Diameter inlet pipe.....
12. Diameter manifold exhaust port.....
13. Make of carburetor.....
14. Size of carburetor.....
15. Rated horsepower.....

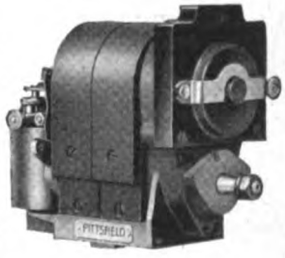
PITTSFIELD

True High Tension Magneto



Most Efficient Sparks at Lowest Speeds

A TRIUMPH in magneto making, the new Pittsfield Perfected Magneto has tremendous power and is simple, strong, efficient, dependable and durable.

There are no moving wires on the armature. Retarded spark is as effective as advanced. No danger of kick-back.

The Pittsfield Engine Starter is a compact little device used in connection with our magneto and starts the motor by simply pressing a button.

Those who have Pittsfield ignition equipment are not annoyed with ignition troubles.

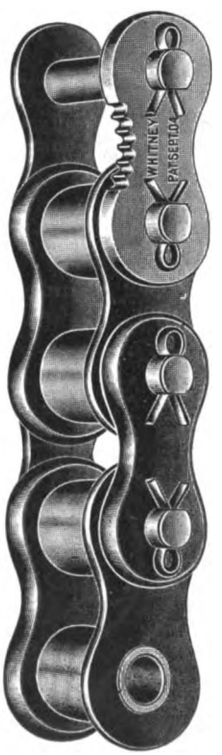
WHITNEY

The Most Practical Chain for Motor Trucks



Because the "Whitney" Cotter Detachable Chain can be easily separated at any link and lengthened, shortened or repaired without the use of any special tool. This is of great advantage to truck builders, owners and drivers.

To have your truck equipped with "Whitney" Chains means greater mileage because they are made by specialists in a factory especially equipped for the making and are backed by years of experience. "Whitney" Chains are made from material chosen for quality regardless of cost, and all care taken in their manufacture makes them stand foremost. When making replacements try a "Whitney" and get acquainted with its merits.

Isn't this good evidence that chain drive is best?

This list, clipped from a leading commercial vehicle paper, tabulates the drives on America's leading commercial cars as exhibited at the Madison Square Garden Show last January. It speaks for itself as to the supremacy of chain drive. It means that more chains are now used than ever and that chain drive is still growing in popularity.

Twenty-two years of constant experimentation and of improvement in machining and metal treating facilities to conform with every advance in metallurgy, enable us to build chain that pulls safely to the highest obtainable tension on the testing machine and in service.

Diamond Chain has justly earned an enviable reputation because of its ability to withstand constant severe duty and to wear well under the hardest weather, road and load conditions of automobile service.

Any user of DIAMOND Chain can tell you of the real superiority in strength, in freedom from serious wear and in the ease of making a repair.

Our engineering department offers free advice on designing problems.

Write for book "Chain Transmission of Power," or if you are a car owner, look for the Diamond trade mark on the side links when you buy your next chain.

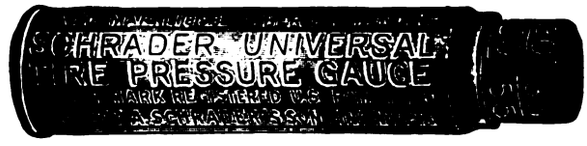
Mr. Automobilist:

Your tire maker is very anxious to impress upon you the importance of

Tires Inflated to the Right Pressure



He insists that this is tire economy and

Saves You Money

How do you know what pressure you have in your tires? A

SCHRADER UNIVERSAL Tire Pressure Gauge

(Trade Mark Registered in U. S. Patent Office)

(Patented March, 1898—Other Patents Pending)

will tell the exact pressure in your tires at any time, day or night, by simply holding this Gauge to your Valve for a second. Its recording sleeve remains in place, showing the exact pressure in the tire so that the Gauge can be taken anywhere and read, at night to the front of the car into the light of the lamps. After the pressure has been ascertained the Indicating Sleeve can be pushed back into the Gauge with your finger. No catches or snaps to operate or get out of order. This Gauge is 2½ inches long over all, short enough to apply easily to the smallest diameter of wheel and can easily be carried in the vest pocket or the change pocket of your trousers.

Price $1.00 Each

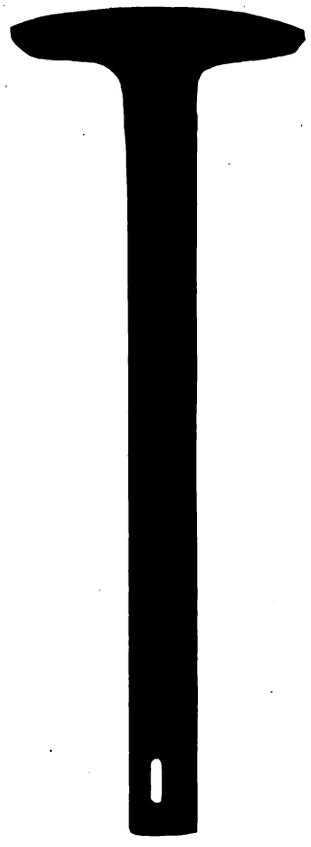
THINK THIS OVER

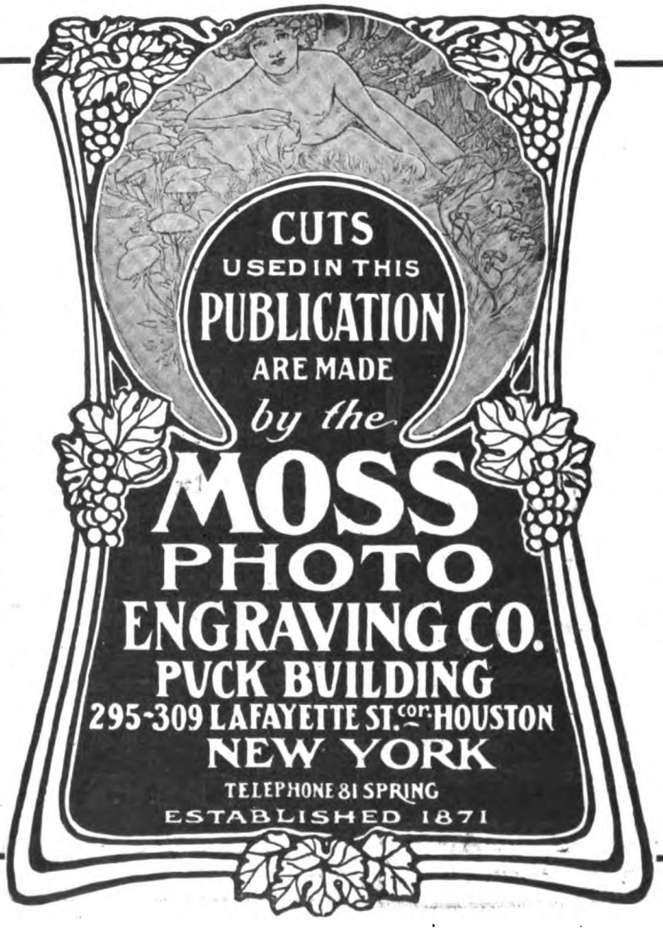
very carefully and read it twice, if necessary.

Is there any part of an automobile engine, or any other gas engine, that is more important to its efficiency than a Valve?

Your engine leaves the factory running smoothly and sweetly—tuned up to its highest power. Perhaps the valves pit—warp—go out of shape—fail to hold compression. Then the power diminishes, and what can be more aggravating to the driver, who has known the fullness of the pulling power of his motor, than to have it grow less and less?



You cannot slight this part by putting in an inferior product—valves that will give trouble, or even break from inexperience in their manufacture—valves of unsuitable material, not suitably heat treated.

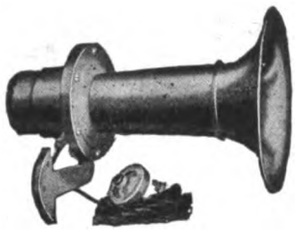


Too much is at stake, and a slight extra cost at the outset, which is the exception, may save you many times over a probable later expense.

This Company, with the experience of many years as a guarantee, will furnish you with properly made valves, of the materials best adapted to your requirements.

Not only QUALITY, but efficient SERVICE is a factor—surely there is a satisfaction in getting the kind of work you want—when you want it.

THE ELECTRIC WELDING PRODUCTS COMPANY
CLEVELAND, OHIO



OUR REPUTATION

is based on the fact that we have been handling the engraving of several prominent trade and general publications for years to the utmost satisfaction of both publishers and advertisers.

SERVICE

The quality of work turned out by this plant is re-inforced by our facilities for deliveries as promised. Your work will be put through with the same care and dispatch given to publishers whose work must be right—and "right on the dot."

Cutting CARS

Get Posted

See our free Table of Comparative Motor Car Values—It will make you a posted purchaser and enable you to form an estimate in your selection of a car that is conservatively the most for the money. **Cutting cars cost less per Horsepower and per Wheel Base Inch than any other automobile selling for $1200 or more.** In point of design, workmanship and finish they are equal, and in some cases superior, to cars selling for from $3000 to $4000.

The Cutting catalog mailed anywhere on request.

CLARKE-CARTER AUTOMOBILE CO.
Jackson, Michigan

If there is no PULLMAN agency in your territory let us hear from you at once. Our 1912 line includes the famous PULLMAN "4-30," "4-35," "4-50" and our two big leaders, the "4-40" and "6-60." The equipment includes self cranking motor, electric lighting device, top, windshield, speedometer, foot and robe rails, etc.

PULLMAN cars "lead the leaders." Some of our agents sell as many as 200 PULLMAN automobiles each year. Let us put you in touch with our agents and find out for yourself why PULLMAN agents are always good agents.

"OUR OFFER"—If there is no PULLMAN agency in your territory we will arrange to "show you" at absolutely no expense to you.

are free from troublesome details, contain more up-to-date features and give more perfect results than others because of our years of experience. We have learned the lessons other makers have yet to learn and our product is proportionately better. Send for catalog.

APPLE ELECTRIC COMPANY
18 N. Canal Street
DAYTON, OHIO, U. S. A.

Franklin Model D

Two types, a five-passenger touring car on a four-passenger torpedo-phaeton — six cylinders, thirty-eight horse-power.

Wheel base 123 inches—ample room for comfort but easy to handle.

Full-elliptic springs and a wood frame—road shocks are absorbed.

Sheet aluminum body—light weight and will not rust, check or crack.

Tires 36 x 4½ inches front, 37 x 5 inches rear—larger than any other car of this size.

Price $3500 for either type.

Write for catalogue for all models.
